EUROPEAN PATENT SPECIFICATION

EP 0 382 764 B1

BACKGROUND OF THE INVENTION

- 5 The invention relates to an integrated system of programming communication and involves the fields of computer processing, computer communications, television, radio, and other electronic communications; the fields of automating the handling, recording, and transmitting of television, radio, computer, and other electronically transmitted programming; and the fields of regulating, metering, and monitoring the availability, use, and usage of such programming.
- 10 For years, television has been recognized as a powerful medium for communicating ideas. Radio and electronic print services such as so-called "tickets" and "broadcast print." But television, radio, and broadcast print are only mass media. Program print media, medium called "broadcast print.") But television, radio, and broadcast print are only mass media. Program content is the same for every viewer.
- For years, computers have been recognized as having unsurpassed capacity for processing and displaying user specific information. But processing is not a mass medium. (Computer is a separate under control of users.
- 15 Today great potential exists for combining the capacity of broadcast media to convey ideas with the capacity of computers to process and output user specific information. New media that result are called "combined" media.
- Unlocking this potential is desired because then new media will add substantial richness and variety to the communication of ideas, information, and entertainment. Understanding complex subjects and making informed decisions will become easier.
- 20 To unlock this potential fully requires means and methods for combining and controlling receiver systems that are now separate-television and computers, radio and computers, broadcast print and computers, television and computers, and broadcast print, etc. It requires capacity for satisfying subscribers who have little apparatus and simple information demands as well as subscribers who have extensive apparatus and complex demands. It requires capacity for transmitting and organizing vastly more information than any one-channel transmission system can possibly convey at one time. It requires capacity for providing reliable audit information to (1) advertisers and others who pay for transmission and (2) copyright holders, pay service operators, and others who demand to be paid. This system must inhibit piracy.
- 25 It is the object of this invention to unlock this potential in the fullest measure by means of an integrated system that joins these capacities most efficiently. It is another object to overcome limitations of the prior art.
- 30 **SUMMARY OF THE INVENTION**
- The present invention consists of an integrated system of methods and apparatus for communicating programming.
- 35 "Programming" refers to everything that is transmitted electronically to entertain, instruct or inform, including television, radio, broadcast print, and computer programming as well as combined medium programming. The system includes capacity for automatically organizing multi-channel communications. Like television and other electronic media, the present invention has capacity for transmitting standardized programming that is simple for subscribers to play and understand. Like computer systems, the present invention has capacity for causing computer to generate and transmit programming and for causing receiver apparatus to operate on the basis of information received at widely separated lines.
- 40 It is the further purpose of this invention to provide means and methods whereby a multipoint transmission (such as a television or radio broadcast) can cause simultaneous generation of user specific information at a plurality of subscriber stations. One advantage is ease of use. For example, a subscriber can cause his information to be processed in complex ways by merely turning his television receive on and tuning to a particular channel. Another advantage is transparency --subscribers see none of the complex processing. Another advantage is privacy. No private information is required at transmitting stations, and no subscriber's information is available at any other subscriber's station.
- 45 It is the further purpose to provide means and methods for automation of intermediate transmission stations that by integrating the broadcast information with each user's information. One advantage of the present invention is to reveal the meaning of complex processing in ways that appear clear and simple. Another is that receiver stations that lack capacity for combining user information into television or radio programming can continue to receive and display the conventional programming.
- 50 It is the further purpose to provide means and methods for automation of intermediate transmission stations that receive and transmit programming. The programming may be delivered by any means including over-the-air ("broadcast") or hard-wire ("cablecast"). The present invention includes capacity for automatically constructing records for each transmitted channel that duplicate the logic that the Federal Communications Commission requires broadcast station operators to maintain.

Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).

If the further purpose to provide means and methods for automation of ultimate receiver stations; for identifying and recording what television, radio, data, and other programming is transmitted at each transmission station, what programming is received at each receiver station, and how programming is used; for recording combined media and/or multi-channel programming and playing back prerecorded programming of such types and for restricting the use of transmitted communications to only authorized subscribers. Such means and methods include techniques whereby the pattern of the composition, timing, and location of signals may vary in fashion that only receiving apparatus that are preformed will be able to process correctly.

The present invention employs signals embedded in programming. Embedded signals cannot become separated inadvertently from the programming and, thereby, inhibit automatic processing. They can be conveniently monitored. A central objective of the present invention is to provide flexibility in regard to station apparatus. The system must have capacity for wide variation in station apparatus in order to provide individual subscribers the widest range of information options at the least cost in terms of installed equipment. Flexibility must exist for expanding the capacity of installed systems by means of transmitted software and for altering installed systems in a modular fashion by adding or removing components. Flexibility must exist for varying techniques that restrict programming to duly authorized subscribers in order to identify and deter pirates.

Other objects, features and advantages of this invention will appear in the following descriptions and appended claims.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

ONE COMBINED MEDIUM

- Fig. 1 shows a video/computer combined medium subscriber station. Via conventional antenna, the station receives a conventional television transmission at television tuner, 215. The Model CV5/10 TV Tuner of Zenith Corporation is one such tuner. This tuner outputs audio and composite video. The audio is inputted to TV monitor, 202M. The video is inputted to decoder, 4, which splits the signal into two paths. One is inputted to TV signal decoder, 203, and the other to microcomputer, 205. Microcomputer, 205, TV signal decoder, 203, described below for receiving a composite video transmission; detecting digital information embedded therein; correcting errors in the received information by means of forward error checking techniques; converting the received information, as may be required, by means of input protocol techniques into digital signals that microcomputer, 205, can receive and process; and transferring said signals to microcomputer, 205. Microcomputer, 205, is a conventional microcomputer system with disk drives that is adapted to have capacity for receiving signals from decoder, 203; for generating computer graphic information; for receiving a composite video transmission; for combining said graphic information onto the video information of said transmission by graphic overlay techniques; and for outputting the resulting combined information to a TV monitor, 202M, in a composite video transmission. One such system is the IBM Personal Computer or IBM Corporation with an IBM Asynchronous Communications Adapter installed in one expansion slot and a PC-Microway Model 1300 System with Tachmar Graphics Master Card, as supplied together by Video Associates Labs of Austin, Texas. Installed in two other slots, Microcomputer, 205, receives digital signals from decoder, 203, at its asynchronous communications adapter and the video transmission from divider, 4, at its PC-Microway System. It outputs composite video at its PC-Microway System. Microcomputer, 205, has all required operating system capacity--e.g., the MS-DOS Version 2.0 Disk Operating System with installed device drivers. TV monitor, 202M, has capacity for receiving composite video and audio transmissions and for presenting a conventional television video image and audio sound. One such monitor is the Model CV 1950 Color Monitor of Zenith Corporation.
- The subscriber station is in New York City and is tuned to the broadcast frequency of channel 13 at 8:30 PM when the station, WNET, commences transmitting a program about stock investing, "Wall Street Week". Said station is an intermediate transmission station for a remote television studio in Maryland. (A station that originates the transmission of programming is called the "program originating studio.") From said studio said program is transmitted by conventional network means to a large number of intermediate transmission stations that retransmit said program to millions of subscribers.
- Microprocessor, 205, contains a conventional 5 1/4" floppy disk at a designated disk drive that holds a data file. Said file containing information on the portfolio of the subscriber that identifies the stocks in the portfolio, the number of shares of each stock and closing share prices. Decoder, 203, is programmed to detect digital information on a line or lines (such as line 20) of the vertical interval of the video input; to correct errors; to convert said information into digital signals usable by microcomputer, 205; and to input said signals to microcomputer, 205, at its asynchronous adapter. Microcomputer, 205, is programmed to receive said input and to respond to instruction signals embedded in the "Wall Street Week" program transmission.
- Other similarly configured and programmed subscriber stations tuning to the transmission of said program, AI each subscriber station, the records in the contained financial portfolio file hold, in identical format, information on the particular investments of that station's subscriber.
- At said program originating studio, a first series of control instructions is generated, embedded sequentially on said line or lines of the vertical interval, and transmitted on each successive frame of said television transmission until said series has been transmitted in full. The instructions of said series are addressed to and control the microcomputer, 205, of each subscriber station.
- In said series--and in any one or more subsequent series of instructions--particular instructions are separated by time periods when no instruction that controls the microcomputer, 205, of any station is transmitted which period is sufficient time for the microcomputer, 205, of each and every subscriber station to complete functions controlled by previously transmitted instructions and commence waiting for a subsequent instruction before receiving a subsequent instruction.
- Tuner, 215, receives this television transmission and transmits the audio to monitor, 202M, and the video via divisor, 4, to microcomputer, 205, and decoder, 203. Decoder, 203, detects the embedded instruction information, corrects it as required, converts it into digital signals usable by microcomputer, 205, and transmits said signals to microcomputer, 205.
- With each step occurring in a fashion well known in the art, this first set of instructions commands microcomputer, 205, (and other subscriber station microcomputers simultaneously) to interrupt the operation of its central processor unit ("CPU") and any designated other processors; then to record the contents of the registers of its CPU and any other designated processors at a designated place in random access memory ("RAM"); then to set its PC-Microway 1300

BRIEF DESCRIPTION OF THE DRAWINGS

BRIEF DESCRIPTION OF THE DRAWINGS

- Fig. 1 is a diagram of a video/computer combined medium receiver station.
- Fig. 1A shows a representative example of a computer generated, user specific graphic as it would appear by itself on the face of a display tube.
- Fig. 1B shows a representative example of a studio graphic combined with a user specific graphic.
- Fig. 2 is a diagram of one embodiment of a signal processor.
- Fig. 2A is a diagram of a TV signal decoder.
- Fig. 2B is a diagram of a radio signal decoder.
- Fig. 2C is a diagram of an other signal decoder.
- Fig. 2D is a diagram of one embodiment of a signal processing system.
- Fig. 2E illustrates the initial binary information of a message.
- Fig. 2F shows one instance of a water-monitor segment.
- Fig. 2G shows one instance of a command.
- Fig. 2H shows the command of Fig. 2G with three padding bits added to complete the last byte signal word.
- Fig. 2I shows one instance of a SPAM message stream.
- Fig. 2J shows one instance of a message that ends one byte signal word.
- Fig. 2K shows one instance of a message that ends with one full byte signal word of padding bits.
- Fig. 3 is a diagram of a video/computer combined medium receiver station with a signal processing system.
- Fig. 3A is a diagram of the preferred controller of a SPAM decoder.
- Fig. 4 is a diagram of one example of a signal processing regulating system.
- Fig. 5 is a diagram of one example of a signal processing monitoring system.
- Fig. 6 is a diagram of one example of a signal processing apparatus at an intermediate transmission station.
- Fig. 7 is a diagram of signal processing apparatus at an ultimate receiver station.
- Fig. 7A is a diagram of signal processing apparatus regulating the environment of the local receiver site.
- Fig. 7B is a diagram of signal processing apparatus used to control a combined medium, multi-channel presentation and monitor viewship.
- Fig. 7C is a diagram of signal processing apparatus selecting information and controlling combined medium, multi-channel presentations.
- Fig. 7D is a diagram of a radio/computer combined medium receiver station.
- Fig. 7E is a diagram of a television/computer combined medium receiver station.
- Fig. 7F is a diagram of an example of controlling television and print combined media.
- Fig. 8 is a diagram of selected apparatus of Fig. 7 with a EEPROM, 205, installed.

to the "GRAPHICS OFF" operating mode in which mode it transmits all received composite video information to monitor, 202M, without modification; then to record information in RAM in an appropriately named file such as "INTERRUPT.BAK" on the contained disk; then to clear all RAM (except that portion containing the operating system) and all registers of said CPU; then to wait for further instructions from decoder, 203.

Under control of said first set, microcomputer, 205, reaches a stage at which the subscriber can input information only under control of signals embedded in the broadcast transmission and can reassert control of microcomputer, 205, only by executing a so-called "warm boot". This set is the "control invoking instructions," and the associated steps are "invoking broadcast control".

Microcomputer, 205, is programmed to evaluate particular initial instructions in each distinct series of received input instructions and to operate in response to said initial instructions.

Subsequently, a second series of instructions is received and transmitted at said program origination studio. Said second series is detected and inputted to microcomputer, 205, in the same fashion as the first series. Microcomputer, 205, evaluates the initial signal word or words which instruct it to load RAM (from the input buffer, to which decoder, 203, inputs) and run the information of a particular set of instructions that follow said word or words. Such a set of instructions that is loaded and run is a "program instruction set." In a fashion well known in the art, microcomputer, 205, loads the binary information of said set in RAM until, in a predetermined fashion, it detects the end of said set, and it executes said set as an assembled, machine language program.

Under control of said program instruction set and accessing the subscriber's contained portfolio data file, microcomputer, 205, calculates the performance of the subscriber's stock portfolio and constructs a graphic image of that performance at the installed graphics card. The instructions cause the computer, first, to determine the aggregate value of the portfolio at each day's close of business by accumulating, for each day, the sum of the products of the number of shares of each stock held times that stock's closing price. The instructions cause microcomputer, 205, to calculate the percentage change in the portfolio's aggregate value for each business day of the week. Then the instructions cause microcomputer, 205, to enter digital information at the video RAM of the graphics card in a pattern that depicts said percentage change as it would be graphed on a graph with a particular origin and set of scaled graph axes. Upon completion, the instructions cause microcomputer, 205, to commence waiting for a subsequent instruction.

If the information at video RAM were to be transmitted alone to the video screen of a TV monitor, it would appear as a line of a designated color, such as red, on a background color, and Fig. 1A shows one such line.

As each subscriber station completes said program instruction set, information of such a line exists at video RAM which information reflects the specific portfolio performance of the user of said station.

While microcomputer, 205, performs these steps, TV monitor, 202M, displays the conventional television image and sound of "Wall Street Week". The host says, "Now as we turn to the graphs, here is what the Dow Jones Industrials did in the week just past, and a studio generated graphic is transmitted. Fig. 1B shows the image of said graphic as it appears on the video screen of TV monitor, 202M. The host says, "And here is what your portfolio did." At this point, an instruction signal is generated at said program origination studio, embedded in the transmission, and transmitted. Said signal is denoted by decoder, 203, transferred to and executed by microcomputer, 205, at the system level as the statement, "GRAPHICS ON". Said signal instructs microcomputer, 205, at the PIC-MicroKey 1300 to overlay the graphic information in its graphics card onto the received composite video information and transmit the combined information to TV monitor, 202M. TV monitor, 202M, then displays the image shown in Fig. 1C which is the microcomputer generated graphic overlaid on the studio generated graphic. Microcomputer, 205, commences waiting for another instruction from decoder, 203.

Simultaneously, each subscriber in a large audience sees his specific performance information as it relates to the performance of the market as a whole.

(An instruction such as "GRAPHICS ON" that causes subscriber station apparatus to execute a combining operation is called a "combining sync command." Said initial signal word or words that preceded the above program instruction set provide another example of a combining sync command in that said word or words synchronized all computers in commanding loading and running.)

As the program proceeds, a further instruction signal is generated at said studio; transmitted; detected; inputted

to microcomputer, 205, and executed as "GRAPHICS OFF." Then said studio ceases transmitting the graphic image, and transmits another image such as the host. Simultaneously, the GRAPHICS OFF command causes microcomputer, 205, to cease overlaying graphic information onto the received composite video and to commence transmitting the received composite video transmission unmodified.

This provides but one of many examples of television based combined medium programming. This television based medium is but one of many combined media.

THE SIGNAL PROCESSOR

In the present invention, the signal processor, Fig. 2, 26 in Fig. 2D; in system, 71, of Fig. 6; 200 in Fig. 7; and elsewhere,-is local means for controlling and monitoring subscriber station operations. It makes communications and enables owners to offer information to subscribers in many fashions on condition of payment. It has capacity for regulating communications consumption by selectively decoupling programming and/or control signals. It has capacity for identifying subject matter of specific programming on each of many channels which enables subscriber stations automatically to tune to particular channels. It has capacity for transferring records automatically to remote stations that bill subscribers on programming usage. It has capacities for processing in other fashions that become apparent in this full specification.

Fig. 2 shows a signal processor configured with a broadcast and a broadcast input. At switch, 1, and mixer, 2 and signal processor, 26, monitors all frequencies available for reception to identify available programming. The inputted information is the entire range of frequencies transmitted on cable and available to a local television antenna. The cable transmission is inputted simultaneously to switch, 1, and mixer, 2. The broadcast transmission is inputted to switch, 1. Switch, 1, and mixers, 2 and 3, are controlled by local oscillator and switch control, 6. Oscillator, 6, is controlled to provide a number of discrete specified frequencies for the particular radio and television channels required. The switch, 1, acts to select the broadcast or cablecast input and passes transmission to mixer, 2, which, with the controlled oscillator, 6, acts to select a television frequency of interest that is passed as a fixed frequency to a TV signal decoder, 30. Simultaneously, mixer, 2, and the controlled oscillator, 6, act to select a radio frequency of interest which is inputted to a radio signal decoder, 40.

At decoders, 30 and 40, digital processor, 26, identifies specific programming and subject matter as said programming becomes available for use and/or viewing. Decoder, 30, shown in Fig. 2A, and decoder, 40, shown in Fig. 2B, detect signal information embedded in the respective inputted television and radio frequencies, encode said information into digital signals that subscriber station apparatus can process, modify, particular, signals through said addition and/or deletion of particular information, and output signals to a TV signal decoder, 30, and a radio signal decoder, 40.

Buffer/comparator, 8, receives signals from said decoders and from other inputs and organizes the received information in a predetermined fashion. Buffer/comparator, 8, has capacity for comparing a portion or portions of inputted information to reprogrammed information and for operating in reprogrammed fashions on the basis of the results of comparing. It has capacity for detecting particular end-of-file signals. In a predetermined fashion, buffer/comparator, 8, determines whether given signal information requires decryption. Buffer/comparator, 8, sends to controller, 26, determine whether signal information requires decryption. Buffer/comparator, 8, sends to controller, 26, so enabled buffer/comparator, 8, transfers said information to decryptor, 10. If not, buffer/comparator, 8, discards said information. Buffer/comparator, 8, transfers signals that do not require decryption to controller, 12.

Decryptor, 10, is a standard digital decryptor that receives signals from buffer/comparator, 8, and under control of controller, 12, uses conventional techniques to decrypt signals. Decryptor, 10, transfers decrypted signals to controller, 12.

Controller, 12, is a standard controller that has microprocessor and RAM capacities and one or more ports for transmitting information to external apparatus. Controller, 12, may contain read only memory ("ROM"). Controller, 12, receives signals from buffer/comparator, 8, and decryptor, 10, analyzes signals in a predetermined fashion; and determines whether they are to be transferred to external equipment or to buffer/comparator, 14, or both. If signals are to be transferred externally, controller, 12, identifies the external apparatus to which the signals are addressed and transfers them. If they contain meter and/or monitor information, controller, 12, selects and transfers appropriate information to buffer/comparator, 14. Controller, 12, has capacity to modify received signals by adding and/or deleting information. Controller, 12, receives time information from clock, 18, and has means to delay signals to delay clock, 18.

Buffer/comparator, 12, receives signal information that is meter and/or monitor information from controller, 12, and organizes said information into meter/records and/or monitor/records in aggregate, "signal records" in predetermined fashions; and transmits signal records to a digital recorder, 16, and/or to one or more remote sites. Buffer/comparator, 8, has capacity to initiate or modify signal records and to discard unnecessary information. To avoid duplicate data, buffer/comparator, 14, has means for counting and/or discarding duplicate instances of signal information and/or incorporating count information into signal records. Buffer/comparator, 14, receives time information from clock, 18, and has means for incorporating time information into signal records. Buffer/comparator, 14, operates under control of controller, 20, and controller, 20, can cause a modification of the formats of and information in signal records at buffer/comparator, 14. Buffer/comparator, 14, may operate under control of a dedicated on-board controller, 14A, which is preprogrammed with appropriate control instructions and is controlled by controller, 20.

Digital recorder, 16, is a memory storage element of standard design that receives information from buffer/comparator, 14, and records said information. In a predetermined fashion, recorder, 16, can determine and inform controller, 20, automatically when it reaches a certain level of fullness.

Signal processor, 26, has a controller device which includes programmable RAM controller, 20; ROM, 21, that may

contain unique digital code information capable of identifying signal processor, 26, and the subscriber station; an automatic dialing device 24; and a telephone unit, 22. A portion of ROM, 21, is erasable programmable ROM ("EPROM") or other form of programmable nonvolatile memory. Under control of particular programmable instructions it is that portion of ROM, 21, that is not erasable, signal processor, 26, has capacity to erase and reprogram said EPROM. Controller, 20, has capacity for controlling the operation of all elements of the signal processor and can receive operating information from said elements. Controller, 20, has capacity to turn off any element of controlled subscriber station apparatus, in whole or in part, and erase any or all parts of erasable memory of said controlled apparatus.

The signal processor of Fig. 2 is but one embodiment of a signal processor. Other embodiments can monitor frequencies other than radio and television through addition of other signal decoders such as that of Fig. 2C below. Embodiments can receive fixed frequencies continuously at decoders. One particular embodiment has no buffer/comparator, 14; recorder, 6; switch, 1; mixers, 2 and 3; or decoders, 30 or 40. Another embodiment has only buffer/comparator, 14; recorder, 16; clock, 18; and the control device apparatus associated with controller, 20. Other embodiments will become apparent in this full specification.

15 SIGNAL DECODERS

Signal decoder apparatus are basic in this invention.

Fig. 2A shows a TV signal decoder that detects signal information embedded in an inputted television frequency. Decoder, 203, in Fig. 1 is one such decoder. Decoder, 30, in Fig. 2 is another. A selected frequency is inputted at a fixed frequency at filter, 31, which defines the channel to be analyzed. The channel signal passes to a standard amplitude demodulator, 32, to define the television base band signal. This base band signal is transferred through separate paths to detector or devices. Path A inputs to a standard line receiver. Said receiver, 33, receives the information of one or more lines normally used to define a television picture. It passes said information to a digital detector, 34, which acts to detect the digital signal information embedded in said information and inputs detected signal information to controller, 35. Path B inputs to a standard audio demodulator, 36, which transfers audio information to high pass filter, 38. Said filter, 36, defines and transfers to digital detector, 37, the portion of said audio information that is of interest. Digital detector, 37, detects signal information embedded in said audio information and inputs detected signal information to controller, 39. Path C inputs to digital detector, 38, which detects signal information embedded in any other portion of said television channel and inputs detected digital information to controller, 39. Line receiver, 33, high pass filter, 38; detectors, 34, 37, and 38; and controller, 39, all operate under control of controller, 39.

Fig. 2B shows a radio signal decoder. Decoder, 40, in Fig. 2 is one such decoder. A selected frequency of interest is inputted at a fixed frequency to standard radio receiver circuitry, 41, which receives the radio information of said frequency and transfers said radio information to radio decoder, 42. Radio decoder, 42, decodes the signal information embedded in said radio information and transfers said decoded information to standard digital detector, 43. Said detector, 43, detects the binary signal information in said decoded information and inputs said signal information to controller, 44. Circuitry, 41; decoder, 42; and detector, 43, all operate under control of controller, 44.

Fig. 2C shows a signal decoder that detects and processes signal information embedded in a frequency other than television or radio. A selected other frequency (such as microwave frequency) is inputted to appropriate other receiver circuitry, 45. Said circuitry, 45, receives and transfers information to detector, 46. Said detector, 46, detects binary signal information and inputs said signal information to controller, 47. Circuitry, 45, and detector, 46, operate under control of controller, 47.

Each decoder is controlled by controller, 39, 44, or 47, that has buffer, microprocessor, ROM, and RAM capacities. The ROM of controller, 39, 44, or 47, may have buffer, microprocessor, ROM, and RAM capacities.

Capable of identifying its controller, 39, 44, or 47, uniquely. Capacity exists at said controller, 39, 44, or 47, for raising said EEPROM, and said RAM and EPROM are reprogrammable. Controller, 39, 44, or 47, is programmed to process any given instance of signal information automatically. Controller, 39, 44, or 47, controls apparatus of its signal decoder and has means for communicating control information to said apparatus. Said controller, 39, 44, or 47, also has means for communicating control information with a controller, 20, of a signal processor, 26.

50 THE SIGNAL PROCESSOR SYSTEM

Signal processing apparatus and methods involve an extended system focused on the signal processor, Fig. 2D, shown one embodiment of a signal processing system. Said system contains signal processor, 26, and antenna decoders, 27, 28, and 29. Each external decoder may be a TV signal decoder (Fig. 2A) or a radio signal decoder (Fig. 2B) or an other signal decoder (Fig. 2C) depending on the nature of the frequency input. Each decoder, 27, 28, and 29, receives one selected frequency and has capacity for transferring deflected, corrected, converted, and possibly modified signals to buffer/comparator, 8, and to other apparatus. Each decoder, 27, 28, and 29, also has capacity for transferring monitor information to buffer/comparator, 14. Controller, 20, has capacity to control all decoder apparatus,

27, 28, 29, 30, and 40.
No every installed decoder requires all the apparatus of Figs. 2A, 2B, and 2C. For example, because a television base band signal is inputted to decoder, 203 of Fig. 1, said decoder does not require filter, 31, and demodulator, 32. Decoders, 27, 28, and 29, communicate monitor information to buffer/comparator, 14, by means of bus, 13.

5 THE SIGNALS OF THE INTEGRATED SYSTEM

Signals are the modalities whereby stations that originate transmissions control handling, generating, and displaying of programming at subscriber stations. ("SPAM" refers to signal processing apparatus and methods of the present invention.) SPAM signals control broadcast stations, cable system headends and media centers. Stations that retransmit transmissions are intermediate transmission stations* and where subscribers view programming are "ultimate receiver stations".
The present invention provides a unified signal system for addressing, controlling, and coordinating all stations and apparatus. One objective is to have capacity to accommodate newly developed hardware while still saving older hardware. This means that the unitized system does not consist of one immutable version of signal composition. Rather it is a family of versions. Accordingly, this specification speaks of "simple preferred embodiment" and "the simplest preferred embodiment" rather than just one preferred embodiment.

10 THE COMPOSITION OF SIGNAL INFORMATION

SPAM signals contain binary information. Fig. 2E shows one example of signal information (excluding bit information required for error correction). The information commences with a header that synchronizes subscriber station apparatus in analysis of the information pattern that follows. Following said header are an execution segment, a meter-monitor segment, and an information segment. The header and execution and meter-monitor segments constitute a command. A command is addressed to particular station apparatus and causes said apparatus to perform a particular function or functions called "controlled functions". Meter-monitor segments cause subscriber station signal processor systems to assemble, record, and transmit meter records and monitor records to remote stations. In the simplest preferred embodiment, all headers consist of two bit binary information, and commands are identified by one of three binary headers:

- 20 10 - a command with an execution segment,
- 25 00 - a command with execution and meter-monitor segments, and
- 35 01 - a command with execution and meter-monitor segments that is followed by an information segment.

Execution segment information includes the subscriber station apparatus that the command addresses and the

controlled functions said apparatus is to perform. "ITS" refers to intermediate transmission station apparatus, and "URS" to ultimate receiver station apparatus. Examples of addressed apparatus include:
ITS controller/computers (73 in Fig. 6),
URS signal processors (200 in Fig. 7), and
URS microcomputers (205 in Fig. 7).

Examples of controlled functions include:

Load and run the contents of the information segments

Commence the video overlay combining designated in the meter-monitor segment, and

Print the contents of the information segment.

Execution segments invoke preprogrammed operating instructions at subscriber station apparatus. For each appropriate addressed apparatus and controlled combination a unique binary value is assigned. In the preferred embodiment, every execution segment contains the same number of bits. The preferred embodiment includes one command called the "pseudo command" that is addressed to no appa-

ratio. By transmitting pseudo command signals, transmission stations cause receiver station apparatus to record meter-monitor segment information without executing controlled functions.

Meter-monitor segments contain meter information and/or monitor information. Examples include:

- 5 meter instructions,
- 6 origins of transmissions,
- unique identifier codes for each program unit (including commercials), and
- 10 codes that identify the subject matter.

For each category, a series of binary bits (a "field") exists in the meter-monitor segment to contain the information. In any given category such as origins of transmissions, each distinct item such as each network source, broadcast, or cable head and station has a unique binary information code. Because the number of categories of meter-monitor information varies from one command to the next, the length of meter-monitor segments varies. Each instance of a meter-monitor segment includes a formal field that contains information that specifies the format of the meter-monitor segment of said instance. Within said field is a group of binary information bits (the "length token") that identifies the number of bits in a meter-monitor segment of said format. Each distinct meter-monitor format also has a unique binary code. Fig. 2f illustrates one instance of a meter-monitor segment (excluding bit information required for error correction). In the preferred embodiment, the bits of the length token are first in each meter-monitor segment.

Information segments follow commands and can be of any length. An information segment can transmit any information that a processor can process.

In the simplest preferred embodiment, a fourth type of header is:

- 11 an additional information segment transmission following a "01" header command and one or more information segments which additional segment is addressed to the same apparatus and invokes the same controlled functions as said "01" command.

An instance of signal information with a "11" header contains no execution segment or meter-monitor segment information.

In the preferred embodiment, "padding bits" render any given SPAM command into a bit length that is complete for communication. Fig. 2H shows three padding bits at the end of the twenty-one bits of the command of Fig 2G. 10 All information transmitted with a given header is called a "message" and a message consists of all the SPAM information from the first bit of one header to the last bit before the next header. The information of any given SPAM transmission consists of a series of headers or streams of messages.

Cadence information which consists of headers, certain length tokens, and "and/or file signals" enables subscriber station apparatus to distinguish each instance of header information in message stream and, hence, the individual messages of said stream. Subscriber station apparatus are preprogrammed to process cadence information. Commands with "10" headers are a header-exec constant length. By preprogramming subscriber station apparatus for processing length token information, the present invention enables said apparatus to determine the bit, following a "00" header, that is the next instance of header information. By programming apparatus to detect and of file signals, the present invention enables said apparatus to determine the bit, following a "01" header, that is the next instance of header information. In the preferred embodiment, an end-of-file signal consists of a sequence of "1" bits (eg. "1111111"). ("1" is an "EOF\$ bit." and "0" is a "MOVE bit.") The length of said sequence (disregarding error correction information) is the minimum necessary to distinguish said sequence. At any given time, alternate lengths exist. One end of file signal is five bytes of EOF\$ bits. Another is eleven bytes of EOF\$ bits. Which is used depends on the nature of the transmission in which said signal occurs.

Fig. 2I depicts one instance of a stream of SPAM messages. Each rectangle represents one signal word. Fig. 2J shows a series of three messages. Each is composed in a whole number of signal words. The first consists of a command followed by padding bits followed by an information segment followed by an end-of-file signal. The second consists of a command followed by padding bits. The third consists of a command alone.

DETECTING END OF FILE SIGNALS

In the present invention, any microprocessor, buffer/comparator, or buffer can be adapted to detect end-of-file signals. At an apparatus so adapted, particular dedicated capacity exists. Said capacity includes three memory locations for comparison purposes, one to serve as a counter, and three to hold triable information. Said locations are the "Word Evaluation Location," "Standard Word Location," "WORD Counter," "WORD Length Location,"

Flag," "Empty Flag," and "Complete Flag" respectively. All operating instructions are preprogrammed as so-called "firmware". Said dedicated capacity is called an "EOF\$ value." The Word Evaluation Location and Standard Word Location and WORD Counter are dynamic memory locations each capable of holding one signal word. The Standard Length Location is one signal memory location capable of holding, at a minimum, one byte. The WORD Flag, Empty Flag, and Complete Flag are each dynamic memory locations capable of holding, at a minimum, one bit. At said Word Evaluation Location is one signal word of received SPAM information. At said Standard Word Location is one signal word of EOF\$ bits. One word of EOF\$ bits is called an "EOF\$ WORD." At the WORD Counter is information of the number of EOF\$ WORDs that said value has received in uninterrupted sequence. Said Flag locations contain "0" or "1" to reflect true or false conditions.

An EOF\$ value receives binary information of one SPAM transmission from one external transferring apparatus and outputs information to one external receiving apparatus.

Determining that an end of file signal has been detected causes said valve to inform external apparatus of the presence of an end-of-file signal. As one example, for apparatus that operates under control of a controller, instructions cause said valve to transmit EOF\$-signal-detected information to said controller then to wait for a control instruction from said controller. Said EOF\$-signal-detected information causes said controller to determine how to process the information at said valve and to transmit either a transmit-and-wait instruction or a discard-and-wait instruction to said valve. Said transmit-and-wait instruction causes said valve to transfer one complete and of file signal then transmit complete-and-waiting information to said controller. Alternatively, said discard-and-wait instruction causes said valve to merely to set the information at said WORD Counter to zero (thereby discarding said end-of-file signal) and transmit complete-and-waiting information to said controller. In the preferred embodiment, said EOF\$-signal-detected information and said complete-and-waiting information are transmitted as interrupts to the CPU of said controller.

In order to define end-of-file signals precisely, a signal word that contains at least one MOVE bit is always transmitted immediately before the uninterrupted sequence of EOF\$ WORDs of any given end-of file signal.

THE NORMAL TRANSMISSION LOCATION

SPAM signals are generated at transmission stations and embedded in television or radio or other programming. In television, the normal transmission location is in the vertical interval of each frame of the television video. In radio, the normal location is in the audio above the range normally audible to the human ear. In broadcasts, print or data communications, the normal location is the same as the conventional information.

OPERATING SIGNAL PROCESSOR SYSTEMS

Five examples focus on subscriber stations where the system of Fig. 1D and the apparatus of Fig. 1 operate in common. Fig. 3 shows one such station. SPAM-controller, 205C, is a control unit like controller, 203, with capacity for transferring information to and receiving from the CPU of microcomputer, 205; and capacity for transferring information to one or more input buffers of microcomputer, 205. SPAM-controller, 205C, has capacity to control directly the PC-Mitsubishi 1300 System.

All five examples relate to the Fig. 1C combining of "One Combined Medium." The first focuses on the basic operation of decoder, 203; SPAM-controller, 205C; and microcomputer, 205. Combined information is displayed at each subscriber station. In the second, the combining of Fig. 1C occurs only at selected subscriber stations. The second combining switch command is partially encrypted, and said stations are preprogrammed to decrypt said command. SSaid command causes said stations to retain meter information. In the third, combined information is displayed at each subscriber station. Monitor information is processed at selected stations for one or more so-called "rating" agents that collect statistics on viewership and programming usage. The fourth example provides a second illustration of selected decoder and metering. Monitor information is collected at selected stations. The fifth example adds signals identified at decoders, 30 and 40, of digital processor, 200. In the last three examples, the first combining switch command causes selected subscriber stations to transfer recorded meter and monitor information and causes computers at remote agencies to receive and process said information.

Each example focuses on three messages. The first is associated with the first combining switch command. Said command has a "01" header, an execution segment and a meter-monitor segment of six fields followed by a program instruction set and an end-of file signal. Said command addresses URS microcomputer, 205. Each meter-monitor field identifies one of the following:

- 55 the origin of said "Wall Street Week" transmission,
- 56 the subject matter of said "Wall Street Week" program,

the program unit of said program.

the day of said transmission.

5 the supplier of the program instruction set, and

the format of said segment.

10 The second message is of the second combining sync command. Said command has a "00" header, an execution segment, a meter-monitor segment of five fields and addresses URS microcomputers. 205. Each meter-monitor field contains information of one of the following:

15 the subject matter of said "Wall Street Week" program,

the program unit of said program,

the unique code of said overlay given said program unit,

20 the minute of said transmission, and

the format of said segment.

The third message is of the third combining sync command. Said command has a "10" header and an execution segment and addresses URS microcomputers. 205. In encrypted commands, meter-monitor segments include an additional field: meter instructions.

All subscriber station apparatus are preprogrammed to perform automatically each step of each example. Recalving SPAM signal information causes subscriber station apparatus to process said information.

At the outset of each example, meter recorder record information of prior programming exists at buffer/comparator. 14. Monitor record information exists at buffer/comparator. 14, associated with the source mark of decoder. 203. Recorder, 16, has reached a level where the next signal record will exceed fullness information.

EXAMPLE # 1

25 The first example begins as divider. 4, starts to transfer, in outputted composite video, the embedded binary information of the first message.

Receiving said information at decoder. 203, which does not include a filter, 31, or a demodulator, 32, because its input is composite video causes line detector, 23, to detect and transfers said embedded information to digital detector, 39, which detects and transfers said binary information with corroding information to controller. 39. Using forward error correction techniques controller, 39 checks said information and corrects it as necessary. Using conversion protocol techniques, controller, 39, converts said corrected information into binary information that receiver station apparatus can receive and process.

(Frequently in this disclosure, specific quantities of bits and bit locations are cited. No attempt is made to account for the presence of parity bits among binary information or at memory locations because techniques for distinguishing and processing bits of communicated information separately from parity bits are well known in the art.)

Said binary information is inputted to the EOFS value of controller. 39.

Recalving the header and execution segment causes controller, 39, to determine that said message is addressed to URS microcomputers. 205. So transferring said message is the controlled function that said header and execution segment cause controller, 39, to perform. As said value transfers converted binary information of said message, controller, 39, selects and records at SPAM-header register memory a preprogrammed constant number of the first working varied bits. Said constant is the number of bits in a SPAM header and is called "H". Controller, 39, determines that information at SPAM+header memory ("01") does not match "11". Not resulting in a match causes controller, 39, to select a second preprogrammed constant number of bits and record said bits at SPAM+exec register memory. Said second constant is the number of bits in a SPAM execution segment and is called "X". Comparing the information at said SPAM+exec memory (the execution segment) with preprogrammed controlled-function-invoking information, controller, 39, determines that said information matches this message-addressed-to-205 information that causes controller,

55 39, to execute preprogrammed transfer-to-205 instructions. Said instruction's cause controller, 39, to determine that

(Whenever comparing execution segment information to controlled-function-invoking information at SPAM apparatus results in a failure to match, said failure causes said apparatus to discard all received information of the message of said execution segment.)

Receiving the header and execution segment causes SPAM controller, 205, to determine the controlled functions that said message instructs URS microcomputers. 205, to perform and to execute the instructions of said functions. SPAM controller, 205C, selects the first H bits and determines that the "01" header does not match "11". Not resulting in a match causes a controller, 39, to select the next X bits and compare the execution segment with controlled-function-invoking-@205 information. A match with execute-sti-205C information causes SPAM controller, 205C, to invoke programmed read-run-and-code instructions that control loading, running, and placing of code information at memory.

10 SPAM controller, 205C, executes said bad-run-and-code instructions.

(No change takes place between controller, 39, and SPAM controller, 205C, in the execution segment of the first combining sync command. This is one of many instances in this specification where a given SPAM command invokes different controlled functions at different apparatus because the apparatus are preprogrammed differently.)

Under control of said instructions, SPAM controller, 205C, must process the length token of a meter-monitor segment. Said instructions cause SPAM controller, 205C, to select a third preprogrammed constant number of bits and record said bits at particular memory. Said constant is the number of bits in a length token and is called "L". Beginning with the bit immediately after the last of said X bits, SPAM controller, 205C, selects L bits and records said bits at SPAM+length-info-@205 register memory. SPAM controller, 205C, compares the information at said memory with preprogrammed token-comparison-@205 information and determines a match. Said match causes SPAM controller, 205C, to place bit-length-number information at raid memory. Said information is the number of bits, following the last of said L bits, that remain in the meter-monitor segment associated with said length token. Said number is one of several preprogrammed bit-length-number information alternatives. The number of the bit-length-number alternative associated with any given length token is called "MMS". And the number of bits in any given meter monitor segment is called "MMS".

EXAMPLE # 1 (SECOND MESSAGE)

Receiving the second message causes controller, 39, to determine that said message is addressed to URS microcomputers, 205. The execution segment involves said transfer-to-205 instructions. The header invokes transfer-00-header-message instructions. Controller, 39, executes process-length-token instructions, select L bits, compare @40 said determined that information at memory matches X-token. Controller, 39, selects bit-length-number information associated with said X-token and place said information at SPAM+length-bit memory. The numeric value of said information is MMS:L. Said transfer-00-header-message instructions cause controller, 39, to add a preprogrammed constant that is the sum of H plus L plus 1 to the information at said memory. Said constant is called "H-X-L". In so doing, controller, 39, determines the number of bits in the command information of said message. Controller, 39, transfers complete binary information of the message.

Receiving said second message causes SPAM controller, 205C, to execute GRAPHICSON ON" at the PC-MicroKey System of microcomputer, 205, if particular conditions are satisfied. The image at video RAM (Fig. 1A) must be relevant to the programming in which said message is embedded. More precisely, program unit and overlay number information must match. SPAM controller, 205C, selects the bits of the meter-monitor format field. Comparing involves process-specific-format instructions. SPAM controller, 205C, places at SPAM+memory-on @205, regular memory information that identifies the format of the meter-monitor segment, execute locate-program-unit instructions and places at first-working memory the information of the program unit field. SPAM controller, 205C, compares the information at said memory. Only which is the program unit identification code of "Wall Street Week", to information at SPAM+bit-precondition register memory. A match causes SPAM controller, 205C, to execute locate-overlays-number instructions. Overwriting the information previously there, SPAM controller, 205C, records the bits of the meter-monitor format field. Comparing involves process-number field. (The information of said field is "00000001") SPAM controller, 205C, compares the information at said memory to "00000001" at SPAM+second-precondition register memory. A match results indicating that microcomputer, 205, has completed placing appropriate Fig. 1A image at video RAM. (At any subscriber station where first-working memory fails to match SPAM+second-precondition memory, the SPAM controller, 205C, interrupts the operation of the CPU of the microcomputer, 205, and transmits restore-sufficiency instructions to said CPU that include information at first-working memory and that cause said microcomputer, 205, in a fashion discussed more fully below, to restore efficient operation.)

EXAMPLE # 1 (THIRD MESSAGE)

The third message is transferred to decoder, 203. The execution segment causes controller, 39, to determine that

said message is addressed to IIRS microcomputers. 205. Controller, 29, compares information at S/PAM-header memory to header-identification information and executes preprogrammed transfer-to-header-message instructions. At any given time, "10" header command information is of one constant length. The aforementioned header+exec constant is "H+X" and is the sum of H plus X. Controller, 39, translates complete information of the message. S/PAM-controller, 205C, executes "GRAPHICS OFF" then transmits a clear-and-continue instruction to the CPU of microcomputer, 205, the function of which is described more fully below.

EXAMPLE #11 A EIGHT MESSAGE

A fourth message illustrates processing an "11" header message. The program originating studio transmits a fourth message. The first two bits of the first signal word d_1 are an "11" header, and the remaining bits are padding bits. The first signal word of the information segment is immediately after said first word. An end of file ends said message.

processes 11-header message instructions that cause controller 39 to execute controlled functions as it the information at SPAM-last-01-header-ex05 register memory were the execution segment of said message. Said information involves at SPAM-last-01-header-ex05 instructions that cause controller 39 to translate said message in the same fashion that applied to the first message of example #1. (If no information were to exist at SPAM-last-01-header-ex05 memory, controller 39 would discard all message information until an end of file signal were received and discarded.)

At SPAM-controller 205C, information at SPAM-last-01-header-ex05 @205 register memory invokes load-unload-and-code instructions. As with said first message, said instructions control the loading, at the main RAM of microcontroller 205, and running of the information segment information. SPAM-controller 205C, executes load-11-header-unload-

卷之三

In example #2, the first and third messages of "Wall Street Week" are transmitted just as in example #1, but the second message is partially encrypted. The execution segment and all of the header/footer segment except the length-token are encrypted, using standard techniques that encrypt binary information without altering the number of bits. The audience information—the "00" header, the length-token, and any padding bits at the end of said messages—remain unencrypted. After encryption, the execution segment is identical to an execution segment that adds RFS signal processors, 200, and instructs said processors, 200, to use a decryption key J and decrypt the message in which said segment occurs.

As described above, before any messages of "Wall Street Week" are transmitted, control invoking instructions command URS microcomputer, 205, to set its PC-Microkey Model 1300 Systems to the "Graphics Off" mode. Thus, at the outset of example #2, no microcomputer, 205, is transmitting combined video to its associated monitor, 202M. When decoder, 203, receives a second message of example #2, controller, 39, determines that said message is addressed to URS signal processors, 200, and transfers said message to buffer/comparator, 8, of signal processor, 200. Said second message causes buffer/comparator, 8, to transfer a portion of the execution segment to programmmable comparison information. A match causes buffer/comparator, 8, to transfer to controller, 20, information that includes information at the header and execution segment. Said information causes controller, 20, to determine a match with decrpt-with-key J information.

(ii) To facilitate processing at stations that are not preprogrammed with necessary decryption key information that the addressee of an otherwise encrypted message must remain unencrypted. Were the header, longhiten or padding bits encrypted, said stations would be unable to locate the header of that following message. Effective SPAM processing would cause until said stations deleted an unencrypted end of file signal.]

Said mark causes controller, 20, to execute decrypt-with-J instructions and to select and transfer key information J to decoder, 10, indicating the header involves decryption-with-J instructions.

controller, 12, transmits to controller, 12, an instruction and mark information that identifies J as the decryption key. Controller, 12, executes programmed transfer-and-meet instructions then records said mark of key J at de-
programmark, 12, egoister memory.

Decryption, 10, commences receiving information, decrypting it using key J and transferring it to controller, 12, to transfer the first H bits without decrypting said bits, 10, to controller, 12, to receive information, decrypt-Q0 header-message instructions cause controller, 10, to transfer the next X bits, to transfer the next L bits, without decrypting said bits, 10, to controller, 12, to determine that said message is addressed to UFS microcontroller, 205, and transfers said mes-
sage to UFS microcontroller, 205, the second combining sync command message "GRAPHICS ON", causing microcom-
puter, 10, to transmit combined programming to monitor, 202H, where Fig. 1C is displayed.

(No second combining sync command reaches microcomputers, 205, at subscriber stations not preprogrammed with decryption key J. When Fig. 1C is displayed at stations preprogrammed with key J, said subscriber stations display Fig. 1B.)

Controller, 12, commences master instructions and causes build/comparator, to add one incrementally to each meter reading at buffer/comparator, 14, associated with information that matches the mark of decryption key J.

Subsequently, decoder, 203, performs the third marking which convolves the third combining sync command. Said command reaches all URS microcomputers, 205, and executes "GRAPHICS OFF". But only at stations preprogrammed with decryption key J does combining cease. All other URS microcomputers, 205, "GRAPHICS OFF" has no effect.

because each of said other [R] microcomputers, 205, is already in 'Graphics Off' mode when said 'Graphics Off' is executed. Significant advantages of simplicity and speed are achieved by devising signal processing apparatus and methods that minimize the need for selective processing. With regard to said third combining sync command, for example, no step of decrypting is required to affect only those stations that are preprogrammed with decryption key J. No possibility exists that an error in decrypting may occur. No possibility exists that some station may take longer than proper to perform the decrypting of said sync command. The time that separates a proper sync command from an improper sync command is negligible.

In the preferred embodiment, controller 39, of decoder 203, and SPAM-controller 205C, are one and the same and are called hereinafter controllers 39.

Fig. 3A shows controller, 39A, Buffer, 39A, and processor, 39B, perform forward error correcting, Buffer, 39C, and processor, 39D, perform protocol conversion. Controlled functions are invoked at control processor, 39J. Having three processors enables controller, 39J, to process information of three words simultaneously.

Each processor, 39B, 39D, and 39J, has RAM and ROM and contains a programmable controller, in its own right. Each processor, 39B, 39D, and 39J, controls its associated buffer, 39A, 39C, and 39E respectively. Each buffer is a conventional buffer. Each buffer, 39A and 39C, transfers its information to its associated processor, 39B and 39D respectively. Buffer, 39E, transfers information via EOFS Valve, 39F, to matrix switch, 39I.

Buffer, 39G, is a conventional buffer with means for receiving information from external inputs, in particular from controller, 12, or signal processor, 200 (the input from controller, 12, to SPAM-controller, 205C, in Fig. 3), Buffer, 39G, outputs information via EOFS Valve, 39H, to matrix switch, 39I. Buffer, 39G, is configured to identify to control processor, 39J, which input is the source of any given instance of information and capacity to output selectively any given instance of received information.

Matrix switch, 391, is a digital matrix switch, well known in the art of telephone switching, that is configured for the small number of inputs and outputs required. Matrix switch, 391, operates under control of control processor, 393, and has capacity to receive information from a multiplicity of inputs, including EOFs Values, 395 and 396, and control processor, 393, and to transformation to a multiplicity of outputs, including control processor, 393, the CPU of microcomputer, 205; buffer/comparator, 8, of signal processor, 200; buffer/comparator, 14, of signal processor, 200; and other outputs. Among such outputs is one or more recall outputs¹ with capacity for rapidly recording information in memory, thereby overwriting information previously recorded (Examples of other outputs are cited below). Matrix for end of file signals.

switch, 39; transfers information without modification, and a multiplicity of transfers can take place simultaneously. The register memories of control processor, 39A, include (but are not limited to) SPAM-input-command register memory whose length in bit locations is sufficient to contain the longest possible instance of SPAM-command information with associated padding bits; the aforementioned SPAM-header and SPAM-axisx register memories; SPAM-Flag-monitor-into, SPAM-Flag-executing-secondary-control-level, [SPAM-Flag-executing-secondary-control-level], SPAM-Flag-secondary-level-incomplete, SPAM-Flag-primary-level-3rd-step-incomplete, SPAM-Flag-primary-level-2nd-step-incomplete, SPAM-Flag-secondary-level-3rd-step-incomplete, SPAM-F-Bg-first-condition-failed, SPAM-Fig-second-condition-failed, SPAM-Fig-don't-care, and SPAM-Flag-working register memories each of which are one bit location in length; SPAM-min-format, particular SPAM-first-precondition, SPAM-second-precondition, SPAM-has-01-hheader-axis register memories; particular SPAM-decryption-mark, SPAM-primary-input-source, SPAM-secondary-input-source, SPAM-next-primary-instruction-address, SPAM-lasi-second-primary-command, SPAM-lasi-secondary-01-header-exc, SPAM-addrs-of-next-instruction-upon-primary-interrupt, and SPAM-address-of-next-instruction-upon-secondary-interrupt register memories whose functions are described below; and a plurality of working register memories. All programmed information associated with controlled functions and instructions that control controller, 39, are programmed at the RAM and/or ROM associated with control processor, 39A.

Control processor, 39J, controls all apparatus of decoder, 203, (except descriptor, 39K) and has capacity for transmitting control instructions to and receiving information from such apparatus. In addition, control processor, 39J, controls the CPU and the PC-Microkey 1300 system of microcomputer, 205, in certain SPAM functions and has capacity via matrix switch, 39L, to transmit and receive control information from said CPU and said system. In certain functions, 5 communication control information directly with controller, 20; the RAM and/or ROM associated with control processor, 39J, are preprogrammed with all information necessary for controlling.

Controller, 39J, has a descriptor, 39K, that is identical to descriptor, 10, of signal processor, 200. Decryptor, 39K, receives information from matrix switch, 39L; outputs to buffer, 39H; has means for communicating control information directly with controller, 20; of signal processor, 200; and is controlled by said controller, 20. Dacrypior, 39K, is preprogrammed and has capacity for processing SPAM message information in fashion described more fully below.

In the preferred embodiment, to maximize speed all apparatus of controller, 39, are located on one microchip.

EXAMPLE #3

Example #3 focuses on selected subscriber stations where signal processing apparatus and methods collect monitor information to so-called program ratings' (such as 'Nielsen ratings') that estimate sizes of audiences. The subscriber station of Fig. 3 is so preprogrammed. The controller, 39, is the preferred embodiment. In all other respects example #3 is identical to Example #1.

When EOF-S valve, 39F, commences transferring the SPAM information of the first message, control processor, 39J, selects the first H bit and compares its information to 11-hourly-invoking information. No match results. Because control processor, 39J, is preprogrammed to process monitor information, instructions cause control processor, 39J, to compare the header with invoke-monitor-processing information. A match signifies the presence of meter-monitor information and causes control processor, 39J, to enter "0" at SPAM-Flag-monitor into register memory.

Control processor, 39J, processes the execution segment. A match causes control processor, 39J, to execute load/run-and-code instructions.

Control processor, 39J, processes the length token then receives all remaining command information and padding bits in said first message. Control processor, 39J, records the information at SPAM-input-signals memory. By receiving all command information and padding bits, control processor, 39J, causes EOF-S valve, 39F, to transfer every signal word in said message prior to the first word of the information at the end of file signal and microcomputer, 205, to commence loading information at the main RAM of microcomputer, 205. Control processor, 39J, to cause transferring information from EOF-S valve, 39F, to control processor, 39J, and commence transferring information from control processor, 39J, to the CPU of microcomputer, 205, transmits an instruction to said CPU that causes said CPU to commence receiving 30 information from matrix switch, 39L, and loading said information in a main RAM; and causes matrix switch, 39L, to commence transferring information from EOF-S valve, 39F, to said CPU.

Then, while EOF-S valve, 39F, processes to detect the end of file signal and microcomputer, 205, loads the program instruction set in RAM, said load/run-and-code instructions cause control processor, 39J, to execute the code portion of said instructions. Control processor, 39J, locates the program unit identification code in the information at said SPAM-input-signals memory and records said code at SPAM-first-precondition register memory. Control processor, 39J, places "1" at SPAM-H-primary-level-3rd-step-incomplete register memory, signifies completion of the code step.

At any point where a station so programmed commands waiting, the control processor, 39J, of the station of processor, 39J, or the station of Fig. 3 to compare SPAM-Flag-monitor into memory with "0". A match results. Said match causes control processor, 39J, to cause matrix switch, 39L, to commence transferring information from control processor, 39J, to buffer/comparator, 14, of signal processor, 200. (said switch is simultaneously transferring information to the CPU of microcomputer, 205); to transfer to said buffer/comparator, 14, header information that identifies a transmission of monitor information then the decoder/203 source mark of said decoder, 203, (which is preprogrammed at control processor, 39J) then received information of said message recorded at said SPAM-input-signals memory. Said received information is the 1st combining sync command, and said information transmitted to buffer/comparator, 14, is the 1st monitor information (#3). Then control processor, 39J, enters "1" at said SPAM-Flag-monitor-info memory, signifying completion of transfer of monitor information.

In due course, EOF-S valve, 39F, receives the end of file signal of said message which causes EOF-S valve, 39F, to transmit EOF-S-detected information to control processor, 39J, as an interrupt signal than commence waiting for an instruction from control processor, 39J.

Receiving an interrupt signal of EOF-S-detected information while under control of controlled function instructions causes control processor, 39J, to enter "0" at buffer/comparator, 14, to enter "0" at SPAM-Flag-monitor-info memory, signifying completion of transfer of monitor information. After executing [GRAPHICS ON], control processor, 39J, compares said memory with "0". A match causes control processor, 39J, to transfer to buffer/comparator, 14, header information that identifies monitor information than the decoder/203 source mark than complete information of the second combining sync command. Said information transmitted to buffer/comparator, 14, is the 2nd monitor information (#3). Control processor, 39J, enters "1" at said SPAM-Flag-monitor-info memory.

Onboard controller, 14A, inputs said 2nd monitor information (#3) to onboard controller, 14A.

Said instructions cause onboard controller, 14A, to record date and time information from clock, 18, at the aforementioned locations that document the date and time respectively of the first and of the last received instances of monitor information of the particular program unit and source mark.

EXAMPLE #3 (SECOND MESSAGE)

The second message of "Wall Street Week" causes control processor, 39J, to enter "0" at SPAM-Flag-monitor-info memory and execute conditional-coverlay-at-205 instructions. After executing [GRAPHICS ON], control processor, 39J, compares said memory with "0". A match causes control processor, 39J, to transfer to buffer/comparator, 14, header information that identifies monitor information than the decoder/203 source mark than complete information of the second combining sync command. Said information transmitted to buffer/comparator, 14, is the 2nd monitor information (#3). Control processor, 39J, enters "1" at said SPAM-Flag-monitor-info memory.

Onboard controller, 14A, records at SPAM-input-signals-#3 register memory all information of said message that was recorded at SPAM-input-signals memory of controller, 39J, and executes process-monitor-info instructions. Said instructions cause onboard controller, 14A, to record date and time information from clock, 18, at the aforementioned locations that document the date and time respectively of the first and of the last received instances of monitor information of the particular program unit and source mark.

litioned last time field of said new monitor record and to compare the monitor format field at SPAM-input-signal-
@ 14A memory to the record format field associated with said monitor record. No match results which indicates that
said 2nd monitor information (#3) contains new information. Onboard controller, 14A, evaluates said now information
and modifies the information content of said new monitor record by adding and/or deleting and/or replacing information.
One element modified is the record format information which is replaced with new record format information. The meter-
monitor information of the minute of the transmission provides new information. By comparing with information from
clock, 18, the controller determines whether "Wall Street Week" is being displayed at the time of its original transmission
or has been "time shifted", that is, recorded at a video tape recorder and played back. If the time is of original trans-
mission, the controller, modifies the second format field with information that distinguishes said new record as a record
of a display of original transmission and enters other information into particular fields of said format. If the original
transmission has been time shifted, the controller modifies the format field with information that distinguishes said new
record as a record of a time shifted display, enters all previously recorded information within the proper fields of said
format, and records the new information or the minute of the transmission. The particular overlay information also
provides new information. The controller records in a field of said new monitor record a count, starting with "1" for said
first overlay, of the number of overlays processed in the course of said program unit. And increments by one a separate
monitor record count of the aggregate number of overlays displayed at monitor, 202M, over a month period.

EXAMPLE #3 (THIRD MESSAGE)

20 The embedded information of the third message of "Wall Street Week" is inputted to decoder, 203. Control pro-
cessor, 39J, selects information of the first X bits after the first H bits, records said information at SPAM-exec memory,
and compares the information at said memory with controlled-function-invoking information. A match results with cease-
overlay information causing control processor, 39J, to execute cease-overlaying-at:205 instructions. Said instructions
cause control processor, 39J, to cause matrix switch, 39J, to commence transferring information from control processor,
39J, to the PC-MicroKey System or microcomputer, 205, to transmit the instruction, "GRAPHICS OFF", to said System;
to cause matrix switch, 39J, to cease transferring information to said System and commence transferring information
from control processor, 39J, to the CPU of microcomputer, 205; to transmit the clear-and-continue instruction (the
function of which is described more fully below) to said CPU; and to cause matrix switch, 39J, to cease transferring
information to said CPU.

25 At the subscriber station of FIG. 3 (and at other stations), said instruction "GRAPHICS OFF" causes said PC-
MicroKey System to cease a combining the programming of FIG. 1A and FIG. 1B and commence transmitting to monitor,
202M, only the composite video received from device, 4, (which causes monitor, 202M, to commence displaying only
said video.) Said clear-and-continue instruction causes microcomputer, 205, to commence processing in a predeter-
mined fashion (which may be determined by the aforementioned program instruction set).

EXAMPLE #4

In example #4, the first and second messages are both partially encrypted, and the combining of FIG. 1A and FIG.
1B occurs only at selected subscriber stations where the information of said messages causes collecting and collecting
of meter information as well as combining. Said messages also cause collecting of monitor information at selected
stations programmed to collect monitor information.

Before the first message is embedded, all of the execution segment, meter-monitor segment, and program instruc-
tion set are encrypted, using standard techniques. After encryption the execution segment is identical to an execution
segment that addresses URS signal processor, 200, and instructs said processors, 200, to use decryption key 2 and
decrypt the message in which said segment occurs.

Receiving said message causes the station of FIG. 3, to decrypt the encrypted portions of said message; execute
the controlled functions of the decrypted information; collect meter information and monitor information relating to said
message; and transfer meter information and monitor information to one or more remote processing stations, causing
said stations to process said information.

40 When EOFs valve, 39F, commences transferring said first message, control processor, 39J, accepts the smallest
number of signal words that can contain H bits; records the information of said words at SPAM-input-signal register
memory; selects information of the first H bits at said memory; records said information at SPAM-hardware memory;
recommences accepting SPAM signal words from EOFs valve, 39F; receives and records words at said SPAM-input-
signal memory in sequence after the information already recorded at said memory; and continues executing control instructions
beginning with that instruction whose location is at SPAM-next-primary-instruction-address memory.

45 The decrypt-and-meter-01-message instructions that begin at said location cause control processor, 39J, to make
Control processor, 39J, causes matrix switch, 39J, to commence transferring information from control processor, 39J,
to buffer/comparator, 14; transfers header information that identifies a meter information then decode-205 source a mark

5 mailon. Said match causes control processor, 39J, to execute preprogrammed transfer-header-and-exec-sign-invo-
200 instructions. Said instructions cause control processor, 39J, to transfer to controller, 20, of signal processor, 200,
via control transmission means, an interrupt signal then particular process this message information then particular
at-39J, information than information of the header and execution segment of said message.

5 Receiving said interrupt signal and information causes controller, 20, to compare the information of said execution
segment to controlled-function-invoking-@200 information and determine if match with decrypt-with-key-2 information
that initiates controller, 20, to cause decryption of said first message with decryption key 2.
(Subscriber stations whose URS signal processors, 200, are not preprogrammed with key 2 discard said message.)
The station of FIG. 3 is preprogrammed to decrypt said message. The at-39J information and match cause controller,
20, to execute decrypt-with-2-at-39J instructions. Said instructions cause controller, 20, to select key information of Z
and transfer said information than a particular decrypt-01-message instruction to decryptor, 39K.

10 Receiving said key information and instruction causes decryptor, 39K, to commence using said key information
as its key for decryption and decrypting inputted information in a 01-header-message fashion.

15 Then said decrypt-with-2-at-39K instructions cause controller, 20, to transmit to control processor, 39J, an instruc-
tion and mark information of Z. Said instruction causes control processor, 39J, to execute decrypt-and-meter-01-mes-
sage instructions. Control processor, 39K, transfers all SPAM information at said SPAM-input-signal memory, then causes
processor, 39J, to commence transferring information from control processor, 39J, to said SPAM-input-signal memory, then causes
matrix switch, 39J, to commence transferring SPAM message information from EOFs valve, 39F, to decryptor, 39K, in
this fashion, control processor, 39J, causes all information of said message to be transferred to decryptor, 39K.

20 Then said instructions cause control processor, 39J, to prepare to execute all secondary control level under primary
control of said instructions, controlled functions invoked by decrypted information. Control processor, 39J, places in-
formation at SPAM-next-primary-instruction-address memory which specifies the location of the next message
and-meter-01-message instruction to execute when control reverts to the primary level; places from-39H information
at SPAM-secondary-input-source register memory; causes matrix switch, 39J, to commence transferring SPAM mes-
sage information from EOFs valve, 39F, to control processor, 39J; places '0' at SPAM-Flag-executing-secondary-
command register memory which signifies information placed subsequently at SPAM-exec memory is secondary com-
mand level information; places '0' at SPAM-Flag-at-second-level register memory which signifies that control func-
tions are being executed at said secondary level; and commands waiting to receive information of a subsequent SPAM
header from switch, 39J.

25 As decryptor, 39K, receives information from matrix switch, 39J, decryptor, 39K, decrypts using key 2 and transfers
decrypted information to buffer, 39G. The decrypt-01-message instruction causes decryptor, 39K, to transfer the first
H bits without decrypting said bits to then to decrypt and transfer information following said H bits.
When EOFs valve, 39H, commences transferring decrypted information of the first message, control processor,
39J, selects information of the first X bits after the first H bits, records said information at SPAM-exec memory, and
30 compares the information at said memory with controlled-function-invoking information. A match causes control pro-
cessor, 39J, to execute load-run-and-code instructions. Said instructions cause control processor, 39J, to receive and
process decrypted length taken information. Control processor, 39J, records additional signal words to receive, records said words in sequence at said SPAM-
input-signal memory, and causes accepting SPAM signal information.

35 Said load-run-and-code instruction cause control processor, 39J, to commence loading. Control processor, 39J,
causes the CPU of microcomputer, 205, to commence receiving information from matrix switch, 39J, and reading said
information at main RAM and causes matrix switch, 39J, to commence transferring information from EOFs valve, 39H,
into memory, determines a particular number of signal words to receive, records said words in sequence at said SPAM-
input-signal memory, and causes accepting SPAM signal information.

40 Said load-run-and-code instruction cause control processor, 39J, to commence loading. Control processor, 39J,
causes the CPU of microcomputer, 205, to commence receiving information from matrix switch, 39J, and reading said
information at the aforementioned SPAM-Flag-at-secondary-control-level memory with '0'. A match re-
sults which means that instructions may exist at the primary control level that control processor, 39J, should execute
before commanding to wait. Said match causes control processor, 39J, to place at SPAM-next-secondary-instruction-
addresses register memory the location of the next instruction to execute when control reverts to secondary level instruc-
tions, place '1' at the SPAM-Flag-at-second-level memory, and commence executing control instructions
beginning with that instruction whose location is at SPAM-next-primary-instruction-address memory.

45 The decrypt-and-meter-01-message instructions that begin at said location cause control processor, 39J, to make
Control processor, 39J, causes matrix switch, 39J, to commence transferring information from control processor, 39J,
to buffer/comparator, 14; transfers header information that identifies a meter information then decode-205 source a mark

information then information of decryption mark Z then all received information of said message recorded at SPAM-input-signal memory, then causes matrix switch 39t, to cease transferring information from control processor 39j to said buffer/comparator, 14. Said received information is the first combining sync command, and said information transmitted to buffer/comparator, 14, is the "1st meter & monitor information" (#4) includes decryption key information, not included in the new monitor record generated by the 1st meter & monitor information (#4) that reflects the presence of said decryption field information.

5 In due course, EOF-S valve, 39f, commences receiving the end of file signal. Said signal causes the subscriber station to cease loading, terminate decrypting, execute the program instruction set information as a machine language program, and commence waiting to receive from EOF-S valve, 39f, the header of a subsequent SPAM message.

10 Receiving said end of file signal causes said EOF-S valve, 39f, to transmit an interrupt signal of EOF-S-signal via control information transmission means, a programmed EOF-S-detect interrupt signal and at 39j information.

15 Receiving said interrupt signal and information causes controller, 20, to execute preprogrammed end-01-or-key-instruction or decryption key 2, to cause decryptor, 39k, to discard said key information of decryption key 2, to cause decrypting, execute the program instruction set information and to commence transferring bill inputted information to and communicate transferring bill inputted information to buffer, 39g, without alteration. Next said instructions cause controller, 20, to transmit a particular programmed transmit EOF-S-signal instruction to control processor, 39j, to transmit the aforementioned transmitt-and-wait instructions to EOF-S valve, 39f.

20 Receiving said transmit EOF-S-signal instruction, causes control processor, 39j, to transfer sequentially eleven instances of EOF-WORD information-that is one complete and of file signal-via switch, 39l, to decryptor, 39k, to transfer said information, without alteration, via buffer, 39g, to EOF WORD information causes decryptor, 39k, to transfer said information.

25 Receiving said information-more precisely, receiving the eleventh instance of an EOF'S WORD in said information-causes EOF-S valve, 39h, to transmit an interrupt signal to control processor, 39j.

Receiving said interrupt signal causes control processor, 39j, to jump and execute the run portion of said load-run-and-code instructions. Automatically, the instructions of said portion cause control processor, 39j, to cause micro-computer, 205, to cause reading information-at main RAM and execute the information so read as so-called "machine executable code".

Running said program instruction set causes microcomputer, 205, (and URS microcomputers, 205, at other stations) to place Fig. 1A image information at video RAM, then cause control processor, 39j, to place "00000001" at SPAM-second-precondition register memory.

Receiving said 1st meter & monitor information (#4) causes buffer/comparator, 14, to compare the header information that identifies a transmission of meter information to programmed header-identification-#14 information. A match results with particular meter-identification information which causes buffer/comparator, 14, to select information of preprogrammed bit locations which contain the meter instruction field of said 1st meter & monitor information (#4) and to compare said selected information to programmed metering-instruction-comparison information. (Matches invoke simple metering processes that buffer/comparator, 14, has capacity to perform by itself). Not resulting in a match causes buffer/comparator, 14, to transfer to controller, 20, particular preprogrammed instruction-set information then said selected information (the meter instruction of said message).

Receiving said information causes controller, 20, to compare said instruction to preprogrammed instruction-set #1@20 information and to determine that said information matches particular 1-2-3-meter information that invokes three sets of instructions programmed at controller, 20. The first set initiates assembly of a second meter record based on the program unit information of said first command. The second set causes assembly of a second meter record based on the supplier of the program instruction set. Under control of said first set controller, 20, initiates assembly of said first record by selecting and placing a particular record locations at buffer/comparator, 14, particular record format information, then program unit information from a meter-monitor field of said 1st meter & monitor information (#4), origin of transmission information from a second field, date and time of processing information from a third field, decryption key information from the decryption 5mark or said 1st meter & monitor information (#4), and finally date and time of processing information from a clock, 18. Controller, 20, executes said second set. Under control of said set, controller, 20, places at record record locations at buffer/comparator, 14, particular record format information, then information of the supplier of said program instruction set from a meter-monitor field of 1st meter & monitor information (#4), program unit information from a second field, origin of transmission information from a third field, date and time of transmission information from a fourth field, and finally date and time of processing information from a clock, 18. Third set causes controller, 20, to cause buffer/comparator, 14, to transfer said second meter record to recorder, 16, then discards said record from its memory and to cause recorder, 16, to record said meter record.

Completing metering functions causes controller, 20, to cause buffer/comparator, 14, to execute its preprogrammed monitoring functions. These functions proceed in the same fashion that applied to the 1st monitor information. The new monitor record generated by the 1st meter & monitor information (#4) includes decryption key information, not included in the new monitor record generated by the 1st monitor information (#4), and record/refresh field information that reflects the presence of said decryption field information.

EXAMPLE #4 (SECOND MESSAGE)

The meter instruction information of the second message of example #4 instructs subscriber stations to perform certain meter operations that are not programmed in example #2. In all other respects the second message of example #4 is identical to the second message of example #2 and is encrypted just as in example #2. Fig. 1A image information exists only at subscriber stations where the first message has been decrypted. Only at said stations does program unit identification code information of "Wall Street Week" exist at SPAM-first-precondition register memories. Only said stations can display Fig. 1C information.

10 Receiving said second message causes the station of Fig. 3 (and other stations) to decrypt the encrypted portions of said message. Control processor, 39j, records X bits at SPAM-exec memory, determines a match with this msg-address-to-200 information, and executes the aforementioned transfer-header-and-exec-to-200 instructions. Controller, 39k, determines a match with decrypt-with-key-j information, selects and transfers key information of J to decryptor, 39k, determines a match with "00" header information, and transmits a preprogrammed process-MMS-L instruction to control processor, 39j. Control processor, 39j, selects information of the first L bit after the first H+X bits, determines the numeric value of MMS-L, and transmits to controller, 20, interrupt information of MMS-L. Controller, 20, transmits to control processor, 39j, decrypt-a-00-header-message instruction which include information of MMS-L and transmits to control processor, 39j, an instruction and decryption mark information of key J. Control processor, 39j, executes decrypt-and-meter-#0-header-message instructions, transfers to decryptor, 39k, complete information of said second message, then prepares to execute a secondary control level controlled functions invoked by decrypted information of said second message causes decryption, 39k, to transfer the first H bits to buffer, 39g, without decrypting said bits, to next MMS-L bits, and to transfer any bits remaining after said MMS-L bits without decrypting said bits remaining. In so doing, decryption, 39k, inputs complete unencrypted information of said message and causes EOF-S valve, 39j, to transfer said information to control processor, 39j.

15 Receiving said information causes control processor, 39j, to compare SPAM-header memory with invoke-monitor processing information and enter "0" at SPAM-Flag-monitor-info register memory; record information of X bits at SPAM-exec memory; determine a match with execute-condition-overwrite-at-205 information and execute conditional-overwrite-at-205 instructions. Said instructions cause control processor, 39j, to receive all remaining information in said second message then prepares to execute a secondary control level controlled functions invoked by decrypted information of said second message causes decryption, 39k, to transfer the program unit field-meter-monitor information of said second message and compare said information to the information at SPAM-first-precondition register memory, causing a match to result.

20 (All subscriber stations where program unit field information fails to match information at SPAM-first-precondition register memory) causes control processor, 39j, to enter "1" at the SPAM-Flag-first-condition-failed and SPAM-Flag-hd-bit-at-205 instructions, cause the control processors, 39j, to enter "1" to cause the main and video RAMs of the microcomputer, 205, to restore efficient operation in a fashion described below. to enter "0" at SPAM-Flag-second-condition-failed and SPAM-Flag-hd-bit-at-205 instructions cause control processor, 39j, then to locate the overlay number field meter-monitor information of said second message and compare said information to the information at SPAM-second-precondition register

25 (All subscriber stations where the overlay number fails to match SPAM-second-precondition memory, conditional-overwrite-at-205 instructions cause control processors, 39j, to interrupt the operation of the CPUJ of the microcomputer, 205, to restore efficient operation in a fashion described below. to enter "0" at SPAM-Flag-second-condition-failed and SPAM-Flag-hd-bit-at-205 instructions cause control processor, 39j, to enter "1" and to complete all controlled functions invoked by said message at the secondary control level.)

Resulting in a match causes control processor, 39j, (and control processors at other stations where matches result) to transfer to the PC-MicroKey System or microcomputer, 205, the instruction GRAPHICS ON and complete all controlled functions invoked at the secondary control level. "GRAPHICS ON" causes said PC-MicroKey System to combine Fig. 1A and Fig. 1B and transmit the combined programming to monitor, 202M, where Fig. 1C is displayed.

30 Completing all controlled functions invoked at secondary control causes control processor, 39j, (and control processors at other stations) to execute the meter portion of said decrypt-and-meter-#0-header-message instructions. Under control said portion, control processor, 39j, compares SPAM-Flag-do-not-meter register memory to "0". No match

results.

- (A) subscriber stations where no matches result, the control processor, 39J, complete all controlled functions invoked by said second message without transferring meter information and, at selected stations, without entering "1" at SPAM-Flag-monitor-into memory. Said selected stations are preprogrammed to collect monitor information.)
- 5 Not resulting in a match causes control processor, 39J, to compare SPAM-Flag-second-condition-failed register memory to "1". A match results.
- (A) stations where no matches result, the control processor, 39J, transfers to the buffer/comparator, 14, header information that identifies a transmission of meter information at a station where no efficient operation of a microcomputer, 205, prevented combining, the decoder-203 source mark, the decryption mark of key J, then all received information of said second message recorded at SPAM-input-augmented memory. Said transmitted information is the "2nd meter-monitor information--second precondition failed"--(#4).)
- 10 Resulting in a match causes control processor, 39J, to transfer to buffer/comparator, 14, header information that identifies a transmission of meter information than the decoder-203 source mark than information of decryption mark of key J then the received information of said second message. Said information that is transmitted to buffer/comparator, 14, is the "2nd meter-monitor information--(#4)." Control processor, 39J, enters "1" at SPAM-Flag-monitor-and-memory and complete all controlled functions of said message.
- 15 Completing the controlled functions of said second message causes control processor, 39J, to compare SPAM-Flag-monitor-into memory with "0". No match results.
- (A) stations where matches result, the control processor, 39J, transfers to the buffer/comparator, 14, header information that identifies a transmission of monitor information at a station where no combining occurred because first precondition program unit information failed to match, the decoder-203 source mark, the decryption mark of key J, than all received information of said second message recorded at the SPAM-input-signal memory. Said information that is transmitted is the "2nd monitor information--(#4).")
- Not resulting in a match causes control processor, 39J, to delete from memory all information of said second message and commence waiting to receive SPAM header.
- 20 Receiving said 2nd meter & monitor information--(#4) causes buffer/comparator, 14, to select information of the meter instruction field or said 2nd meter & monitor information--(#4) and transmit to controller, 20, instruct-to-meter information that said meter instruction information.
- Receiving said information causes controller, 20, to execute update-and-increment instructions. Said instructions cause signal processor, 200, to modify the first meter record initiated by the 1st meter & monitor information--(#4).
- 25 Executing said instructions causes controller, 20, to place information of the overlay number field at a record field associated with said 1st meter record, signifying the combining of said overlay at the subscriber station, place, at the record location occupied by format information, new format information to increment by one the meter record associated with each decryption-key-comparison datum that matches the decryption mark of said 2nd meter & monitor information--(#4), and to complete said update-and-increment instructions.
- Completing the metering functions causes controller, 20, to cause buffer/comparator, 14, to execute monitoring functions. These functions proceed in the fashion of the 2nd monitor information--(#3). Onboard controller, 14A, includes decryption key information of J.
- (A) each station where the aforementioned 2nd meter & monitor information--second precondition failed--(--#4) is transmitted, said 2nd information invokes two sets of instructions preprogrammed at controller, 20. The first set causes the decryption mark of said 2nd information to be added to each meter record associated with decryption key information that matches the decryption mark of said 2nd information. The second set causes controller, 20, to assemble a record of a failed combining and record said record at recorder, 16. Said record includes information that identifies said record as information of combining above due to inefficient operation of a microcomputer, 205, the unique digital code of the subscriber station, and the program unit identification code and overlay number information of said second message. Each station preprogrammed to collect monitor information executes monitoring functions. Those proceed in the fashion of the 2nd meter & monitor information--(#4) with exceptions. The onboard controller, 14A, adds information that combining failed to occur because of inefficient microcomputer operation and the information of the overlay number field.)
- (A) each station where the aforementioned 2nd monitor information--(#4) is transmitted, no 1st meter & monitor information--(#4) transmission occurred. Accordingly, said 2nd monitor information--(#4) causes the station to process information in the fashion of the 1st monitor information--(#3). The signal processor, 200, records a record of prior programming at recorder, 16, and initiates a new monitor record that reflects the "Wall Street Week" programming. Signal processor, 200, assembles said monitor record in the format of a combined video/computer/medium transmission at a duration where no combining occurred because first precondition program unit information failed. At particular record locations are the program unit identification code of the "Wall Street Week"; the overlay number; the minute of "Wall Street Week" program transmission within a one month period; a display unit identification code that identifies monitor, 202M, as the display apparatus; and date and time information from clock, 18.)

EXAMPLE #4 (THIRD MESSAGE)

- Subsequently, the embedded information of the third message of "Wall Street Week" is inputted to decoder, 203. Said information is identical to the embedded information of the third message of example #3 and causes the same processing. The third message causes "GRAPHICS OFF" to be executed at the microcomputers, 205, of all subscriber stations tuned to the "Wall Street Week" transmission. But the third message of example #4 causes combining actually to cease only at selected stations where information of the second message previously caused combining to commence; that is, only at those stations preprogrammed not only with information of decryption key J but also information of decryption key Z.
- 5 Example #5 focuses on program unit identification signals detected at decoders, 30 and 40. Signal processor, 200, is preprogrammed with information that identifies each transmission in the locality. Controller, 20, controls oscillator, 6, to sequence in the pattern: cable channel 2, 4, 7, 13, wireless channel 5, 8, then repeat said pattern.
- Example #5 begins with broadcast of the first message of "Wall Street Week". Nixon, 3, selects the frequency of channel 12 and inputs said frequency to decoder, 30. Receiving said frequency causes decoder, 30, (which is shown in detail in Fig. 2A and whose controller, 39, is shown in Fig. 3A) to receive the first combining sync command and record said command at the SPAM-input-signal memory of control processor, 39J.
- 20 Decoder, 30, is programmed to process said information as monitor information and local control information. Receiving said command causes control processor, 39J, to locate monitor information in RAM associated with the channel mark of cable channel 13 and compare the program unit identification code of said command with the program unit information of said information. No match results which indicates cable channel 13 is transmitting a new program unit. Not resulting in a match causes said controller, 39, to transfer said information in RAM which is monitor information of the program transmitted on cable channel 13 prior to "Wall Street Week". Control processor, 39J, transmits a message that consists of "00" to have then the execution agent information in the pseud command than a meter-monitor segment containing said monitor information. Said message is the "1st-old-program" (#5). Control processor, 39J, determines that said first command contains subject matter meter & monitor information causing control processor, 39J, to transmit a message that consists of "00" to have then the execution agent information addressed to microcomputer, 205, then meter-monitor segment information that includes the program unit identification code and subject matter information of said first command and the channel mark of cable channel 13. Said message is the "1st-new-program" (#5"). Control processor, 39J, records at RAM, with said mark, meter-monitor information of said first command. Controller, 39J, transmits detection-complete information to controller, 20.
- 25 Receiving detection-complete information causes controller, 20, to cause selection of wireless channel 5. The selection that follows on wireless channel 5 is addressed to TS control/interpreter, 73. Nevertheless, control processor, 39J, of decoder, 30, has capacity to process the meter-monitor information of said command. Receiving said command causes control processor, 39J, to transfer to buffer/comparator, 8, a message called the "2nd-old-program" (#5). When the input of wireless channel 9 to decoder, 30, commences, the remote wireless station is transmitting no signal information in the normal transmission pattern. Determining that a particular period of time has elapsed causes selection of cable channel 13.
- 30 While decoder, 30, is processing video transmissions, radio signal decoder, 40, is processing radio transmissions inputted from mixer, 2. (Decoder, 40, is shown in detail in Fig. 2B. Controller, 44, is identical to controller, 39, of Fig. 3A.) In the example, buffer/comparator, 8, receives from decoder, 30, 1st-, 2nd-, and 3rd-old-program (#5) messages and the 1st-new-program (#5) and from decoder, 40, 1st-old-radio-program (#5) and 1st-new-radio-program (#5) messages. All are commands. The 1st-new-program (#5) informs microcomputer, 205, of new programming to which said microcomputer can tune station apparatus in fashions described below. Said command is a "guide command". The 2nd-old-program (#5) and the 1st-old-program (#5) are addressed to no apparatus. Each is a transparent command.
- 35 Each guide command involves instructions that cause controller, 12, to input the message of said command to buffer, 39G, of controller, 39, of decoder, 203. Each transparent command invokes no controlled function. In example #5, controller, 12, is programmed to process monitor information. After transmitting or determining that each command invokes no controlled function, controller, 12, transfers to buffer/comparator, 14, header information that identifies a transmission of monitor information of available programming then all information recorded at said SPAM-input-signal memory. Signal processor, 200, processes the monitor information in a fashion that is similar to examples #3 and #4.
- 40 Receiving a new programming message causes signal processor, 200, to record a record at recorder, 16.

SIGNAL-RECORD TRANSFER

In each example, when recorder, 16, finishes recording signal record information, recorder, 16, measures the quantity of its records and determines that said quantity is greater than fullness information. Said determining causes recorder, 16, to transfer an instruction-call instruction that causes controller, 20, to activate telephone connection, 22, and transfer information to a computer at a remote station. Controller, 20, transfers the telephone number, 1-800-AUDITOR, and causes diafer, 24, to dial said number. Said computer answers, and controller, 20, transfers the unique digital identifying code of ROM, 21. Controller, 20, causes recorder, 16, to transmit records to said computer then to erase record information.

REGULATING RECEPTION AND USE OF PROGRAMMING

The present invention includes other means and methods for regulating reception and use of programming. The computer system of the present invention has capacity to compute station specific information based on programmed information that exists at each station and differs from station to station. Given this capacity, any central control station can cause subscriber stations to decrypt received SPAM information in different fashions with each station decrypting its received information in its own fashion. A central station can cause stations to compute station specific decryption cipher keys and/or algorithms and/or information that differs from station to station and controls each station in identifying which key and/or algorithm to use for any given step of decrypting. A second feature is that effective processing depends on the correspondence between the transmitted SPAM information that causes processing and the information programmed at the stations that controls processing. In order for an executor segment to invoke an controlled function at any given station, the received binary information (‘‘010011’’) that this feature permits each station to be programmed with station specific controlled-function-invoking information that differs from station to station. The third feature is an extended system of means and methods for regulating the reception and use of SPAM information-including decryption key and algorithm information--that is illustrated in Fig. 4.

By themselves, the first and second features provide a technique whereby a message can affect selected stations without being decrypted at said stations. This technique is ‘‘covert control.’’ Example #6, which is set in the context of example #4, illustrates covert control. In example #4, the execution segment of the second message, when decrypted, is, for example, ‘‘100110.’’ And the execute-condition-overlays-at-205 information that said segment matches is also ‘‘100110.’’ In example #6, the execution segment of said second message is ‘‘111111.’’ Two messages are transmitted. Each consists of a ‘‘01’’ header, execution, meter-monitor, and information segments, and an and or like signal. Said messages are the ‘‘1st supplementary message (#6)’’ and the ‘‘2nd supplementary message (#6).’’ Each is encrypted prior to transmission in the fashion of the first message of example #4 except that encryption is done with key J.

The ‘‘Wall Street Week’’ program originating studio embeds and transmits the 1st supplementary message (#6) before transmitting said second message. Just as with the first message of example #4, a stations preprogrammed with decryption key J, the 1st supplementary message (#6) causes the station to decrypt said message using key J and execute controlled functions involved in the decrypted execution segment. A match occurs with execute-set-39J information that causes control processor, 39J, to execute load-and-run 39J instructions. Control processor, 39J, loads the information segment at RAM associated with control processor, 39J, the end of file signal causes EOFs value, 39H, to transmit the interrupt signal of EOFs-signals-decided information. Said signal causes control processor, 39J, to execute the information at RAM as a machine language job. Said information causes control processor, 39J, to locate the location of that instance of controlled-function-invoking information that is ‘‘100110’’ (the execute-condition-overlays-at-205 information) and modify the information at said location to ‘‘111111.’’

When the second message of the ‘‘Wall Street Week’’ program of example #6 is transmitted with its ‘‘111111’’ execution segment, said message is processed at stations that are preprogrammed with decryption key J precisely as the second message of example #3 is processed. (At all other stations, said message is automatically discarded because ‘‘111111’’ fails to match any controlled-function-invoking information.)

The ‘‘Wall Street Week’’ program originating studio embeds and transmits the 2nd supplementary message (#6) after transmitting said second message. At stations preprogrammed with key J, said message causes control processor, 39J, to locate the controlled-function-invoking information that is ‘‘111111’’ and modify the information at the location of said ‘‘111111’’ to ‘‘000110.’’ Covert control provides significant benefits. One benefit is speed. No time is spent decrypting messages (such as the second message of example #4) that convey control commands. Thus the shortest interval of time can exist between the moment when a combining sync command is embedded and the moment when it causes combining at selected stations. A second benefit arises out of its capacity to repeat. After transmitting said 1st supplementary

message (#6), the program originating studio can invoke the aforementioned conditional-overlays-at-205 instructions at said selected stations many times by transmitting execution segments that are ‘‘111111’’ before transmitting said 2nd supplementary message (#6).

Fig. 4 shows the Programming Reception and Use Regulating System of the present invention. The subscriber station has capacity for receiving wireless transmissions at a conventional antenna, 195, and a cable transmission at converter boxes, 201 and 222. Said boxes, 201 and 222, are conventional cable converter boxes with capacity for receiving information of a selected channel of a multi-channel transmission and converting the selected information to a given output frequency. The channels are selected by tuners, 214 and 223 which are conventional tuners. Antenna, 195, and boxes, 201 and 222, transmit to matrix switch, 258, which is a conventional matrix switch. One apparatus 10 said switch has capacity for outputting to a television tuner, 215. The configuration of Fig. 4 differs from Figs. 1 and 3 in that television tuner, 215, outputs its audio and video to said matrix switch, 258. In Fig. 4, said switch, 1

outputs the input to said monitor, 202M, and divisor, 4. Fig. 4 shows five additional devices. Decyphote, 107, 224 and 231, are conventional decyphotes with capacity for outputting digital information, decyphering by means of a selected cipher algorithm and a selected cipher key, and outputting decrypted information. Signal stripper, 229, is a conventional signal stripper with capacity for receiving transmission of video information, removing embedded signal information selectively, and outputting the removed information. Signal generator, 230, is a conventional signal inserter, with capacity for receiving a transmission of video information, embedding signal information selectively, and outputting the transmission with the embedded information. Matrix switch, 258, has capacity for outputting selected transmissions to each said device, and each of said devices outputs its information to said switch 258.

As Fig. 4 shows, signal processor, 200, controls all the aforementioned apparatus. Signal processor, 200, controls the tuning of tuner, 214, 215, and 223, controls the switching of switch, 258, supplies cipher algorithm and cipher key information to and controls decyphote, 107, 224 and 230; controls digital stripper, 229, in selecting transmission locations and/or information to strip and in stripping; and controls signal generator, 230, in selecting transmission locations 15 and/or information to strip and in stripping; and controls signal generator, 230, in selecting transmission locations 230; at which to insert signals, in generating specific signals and in inserting.

Fig. 4 also shows divisor, 4, monitor, 202M, decoder, 203, and microcomputer, 205, which function and are controlled as in Figs. 1 and 3. Finally, Fig. 4 shows local input, 225, which means for generating and transmitting control information to controller, 20, of signal processor, 200. In the preferred embodiment, local input, 225, is activated by keys that are depressed manually by the subscriber in the fashion of a touch-tone telephone or microcomputer keyboard. As Fig. 4 shows, microcomputer, 205, has capacity for inputting control information via decoder, 203, to said controller, 20.

EXAMPLE #7

Example #7 illustrates operation of the system of Fig. 4. The program originating studio that originates ‘‘Wall Street Week’’ transmits a television signal of video and digital audio in clear to intermediate transmission stations. The intermediate station that retransmits ‘‘Wall Street Week’’ to the subscriber of Fig. 4 is a cable system head and [such as Fig. 6]. Prior to retransmission, said station encrypts the digital audio from the cable channel 13 at 8:30 PM.

In example #7, controller, 20, of signal processor, 200, is programmed with information that the subscriber wishes to view ‘‘Wall Street Week.’’ So programming controller, 20, can occur in several fashions. For example, a subscriber may enter please-fully-enable-WSW-on-CC1-3-at-particular-8:30-information and cause said program on cable channel 13 and, in a fashion described more fully below, caused to input please-fully-enable-WSW-on-CC1-3-at-particular-8:30-information to controller, 20.

Receiving any given instance of please-enable-WSW-on-CC1-3-at-8:30-information causes controller, 20, to execute particular receive authorizing-code instructions. At a particular command-enabling time, controller, 20, transmits preprogrammed enable-next-CC1-13 information to the control processor, 39J, or decoder, 30, and causes said control processor, 39J, to place one instance of said information at a particular controlled-function-invoking information location, causes switch, 1, and mixer, 3, to select a particular maleable control channel to input to decoder, 30, causes control processor, 39J, to cause line receiver, 33, and digital detector, 34, to commence inputting to controller, 39, SPAM information delineated in the input; and places one instance of said enable-next-CC1-13 information at a particular controlled-function-invoking-#20 information location.

In the interval between said command-enabling line and 8:30 PM said head end is caused to transmit a SPAM message that consists of a ‘‘01’’ header, execution segment information that matches said enable-next-CC1-3 information, information and segment information of particular enable-CC1-13 instructions that include enable-WSW-programming information, and an end of file signal on said master control channel. Said message is the ‘‘local-cable-enabling-message’’ (#7).*

Said message causes decoder, 30, to select information of the execution segment and determine that said information matches the enable-not-Cc13 information at said controlled-function-invoking information location. Determining that a match causes the control processor, 39A, to execute transfer-thru-message-to-controller-20 instructions that are associated with said location. The matrix switch, 39J, of decoder, 30, has capacity to transfer information to controller, 20, via control transmission means and executing said instructions causes control processor, 38J, to transfer said message to controller, 20.

Receiving said message causes controller, 20, to load the enable-CC13 instructions at RAM of controller, 20, and execute said instructions.

Said instructions cause controller, 20, to sample selected programmed SPAM information and determine whether unauthorized tampering has occurred. Controller, 20, selects information of the unique digital code at ROM, 21; branches to a selected subroutine of said instructions on the basis of the value of said integer, and executes said subroutine. Said subroutine causes controller, 20, to select information of sixteen contiguous bit locations that contain information of said enable-CC13 instructions and compare said selected information to information of sixteen contiguous bit locations at a signal processing RAM or ROM at the station. A match indicates that said bit locations are programmed properly. A match occurs.

(Simultaneously, other stations compare. At each station where a match fails to occur, not resulting in a match causes the controller, 20, to release particular RAM, then to cause auto dialer, 24, and telephone connection, 22, to establish telephone communications with a remote station, then to transmit information of the unique digital code at ROM, 21, as well as particular appearance-of-tampering information.)

Resulting in a match causes controller, 20, to execute a portion of said enable-CC13 instructions. Said portion causes selected apparatus to receive the cable channel 13 transmission, decrypt the audio, commence waiting to receive further enabling information, and create a meter record. Controller, 20, causes matrix switch, 258, to cease transferring video and audio to monitor, 202M. Then controller, 20, causes tuner, 214, to tune to the frequency of cable channel 13, thereby causing its associated converter box, 201M, to convert information of said frequency to a selected output frequency and transfer said information at said frequency to matrix switch, 258. Controller, 20, causes matrix switch, 258, to transfer information from box, 201M, to television tuner, 215, and causes tuner, 215, to tune to said selected frequency, thereby causing said tuner, 215, to receive cable channel 13 and output the audio and video portions of said information to matrix switch, 258, on the separate audio and video outputs of tuner, 215. Controller, 20, causes matrix switch, 258, to transfer the audio inputted from tuner, 215, to decoder, 107, thereby causing deciphering, 107, to receive the encrypted digital audio. Controller, 20, selects information of cipher key Ca; transfers said key information to decipher, 107, and causes decipher, 107, to commence decoding its received audio information, using said key and decryption cipher algorithm C, and outputting decrypted information of the audio of "Wall Street Week". To matrix switch, 258. Controller, 20, causes matrix switch, 258, to transfer information from decipher, 107, to signal processor, 200, thereby causing signal processor, 200, to receive said information at a particular third contact of switch, 1, (not shown in Fig. 2). Controller, 20, causes switch, 1, to connect to said third contact, and mixer, 3, to transfer said information without modification, causes the control processor, 39J, of decoder, 30, to cause the filter, 31, and demodulator, 32, to transfer said information without modification; causes said control processor, 39J, to cause digital deflector, 38, to commence waiting to receive header information. Then said instructions cause controller, 20, to cause control processor, 39J, to place one instance of said enable-WSW-programming information (that said instructions include) at the controlled-function-invoking information location occupied by said enable-next-CC15 information (thereby overwriting said information) and cause controller, 20, to place one instance of said enable-WSW-programming information at the controlled-function-invoking-@20 information location occupied by said enable-next-CC13 information. Finally, in the fashion of the first message of example #4, controller, 20, causes information of the meter-monitor segment to be placed at particular locations of buffer/comparator, 14, thereby creating a molar record that records the description of the audio portion of "Wall Street Week".

Subsequently, said program originating studio embeds a SPAM message that consists

of a "01" header, execution segment information that matches said enable-WSW-programming information, meter-

monitor information, 1st-stage-enable-WSW-program instructions that are information segment information, and an end

of file signal. Said message is the 1st-WSW-program-enabling-message (#7).

Signal processor, 200, detects and transfers said message to controller, 20. Controller, 20, executes the 1st-allegeable-WSW-program instructions a machine language job. Said instructions cause controller, 20, to affect a first stage of decrypting video of "Wall Street Week". Controller, 20, selects the last three significant digits of the unique digital code at ROM, 21; computes that Q quantity that is 16 less than the product of multiplying the numerical information of said digits times 256; and deflects information of the sixteen contiguous bit locations at the RAM associated with control processor, 39J, that commence at the first bit location that is said Q locations after a particular first location at said RAM. At the station of Fig. 4, the programmed information of said sixteen contiguous bit locations is decryption

cipher key Ba. In the present invention, the preferred method of preprogramming signal processing apparatus is to vary locations of information from station to station. The controller, 20, causes decipher, 107, to commence decrypting received information, using said key information and selected decryption cipher algorithm B. Controller, 20, causes matrix switch, 258, to transfer video from tuner, 215, to decipher, 107, and from decipher, 107, to the third contact of switch, 1.

In due course, said studio embeds in the video and transmits a check sequence of binary information called the "1st-WSW-decrypt-on-check" (#7). Then said studio causes transmitting digital video and digital audio.

Said sequence causes controller, 20, to compare selected information of said sequence to selected information of said 1st-stage-enable-WSW-program instructions. A match occurs, 4, indicating that decipher, 107, is decrypting correctly.

(Simultaneously, other stations compare. Each station where a match fails to occur erases RAM, establishes telephone communications, and transmits appearance-of-tampering information with the unique digital code that identifies said station.)

A match causes controller, 20, to execute a portion of said 1st-stage-enable-WSW-program instructions. Said portion causes the station to cease receiving and decrypting digital video and audio, to commence receiving analog television, and to prepare to receive particular embedded SPAM information at the decoder, 30, of signal processor, 200. Controller, 20, selects the first three of the last four significant digits of the unique digital code at ROM, 21; computes that Q quantity that is the sum of the numerical information of said three digits plus 20, and causes decoder, 30, to commence receiving information embedded on the line Q (and only on line Q) of the inputted video. (In other words, if the binary information of said three digits is "000", decoder, 30, receives information embedded on line 20; if the binary information of said three digits is "001", decoder, 30, receives information embedded on line 21; etc.)

In due course, said studio communicates transmitting analog television and embeds SPAM message information on lines 21, 22, 23, 24, 25, and 27. On each line said station transmits one particular message. Each message consists of a "01" header, execution segment information that matches said enable-WSW-programming information, and meter-monitor information, 2nd-stage-enable-WSW-program instructions as the information segment information, and an end of file signal. Each of said messages is identical, except as regards certain differences in said 2nd-stage-enable-WSW-program instructions described below. Prior to being embedded each message is encrypted. Each message is called a "2nd-WSW-program-enabling-message" (#7). Then said program originating studio erases transmitting analog television.

Decoder, 30, receives the 2nd-WSW-program-enabling-message (#7) embedded on said line Q. Control processor, 39J, causes controller, 20, to cause the decoder, 30, to decrypt said message. EOFs valve, 39H, inputs said message, unencrypted to control processor, 39J. Control processor, 39J, transfers said message to controller, 20. Controller, 20, executes the 2nd-stage-enable-WSW-program instructions.

Said 2nd-stage-enable-WSW-program instructions cause controller, 20, to strip information from "Wall Street Week", insert information, and affect a second stage of decrypting. Controller, 20, causes matrix switch, 258, to cease transferring information to said third contact; commence transferring information from decipher, 124, to signal stripper, 229; transfer from stripper, 229, to signal generator, 230; to decipher, 231; and transfer from decipher, 231, to said third contact of switch, 1. Controller, 20, causes signal stripper, 229, to strip information from a strip-designated portion of the video transmission and transfer the video without said stripped information to matrix switch, 258. Said stripped information may be information that would cause disabling chips to prevent microcomputer, 205, or monitor, 202M, from processing or displaying the video. (Controller, 20, strips compiler information off of the unique digital code at ROM, 21, and causes generator, 230, to insert said information in a periodic fashion into the insertion-designated portion of the video transmission and to transfer the video with said inserted information to matrix switch, 258. (If pirated copies are distributed, in the nation at which decryption occurred can be identified.) Controller, 20, selects the aforementioned first three of the last four significant digits of the unique digital code at ROM, 21 and computes a Q quantity according to a formula in said 2nd-stage-enable-WSW-program instructions. Said Q quantity is the decryption key Ra. (The formula in the right different 2nd-WSW-program-enabling-message (#7) messages differ in such a way that when each station computes its own unique digital code digits, the Q quantities computed at all properly preprogrammed and functioning stations are identical.)

In due course, said studio encrypts and transmits in digital video a check sequence of binary information followed by an end of file signal. Said check information is the "2nd-WSW-decrypt-on-check" (#7). Selected information causes controller, 20, to determine a signal stripper, 229, is correctly stripping and signal generator, 230, is correctly inserting (Other stations compare selected information. At each station where a match does not result, instructions cause said station to establish telephone communications then transmit appearance-of-tampering information with the unique digital code that identifies said station.)

Determining that stripper, 229, and generator, 230, are stripping and inserting correctly causes the station (and all other stations where so determining) to transfer television information of "Wall Street Week" to microcomputer, 205, and monitor, 202M. Controller, 20, causes matrix switch, 258, to transfer audio from decipher, 107, to monitor,

2024M, causing monitor, 202M, to commence receiving audio and emitting sound. Controller, 20, causes matrix switch, 258, to commence transferring video from decoder, 23, to divider, 4, causing divider, 4, to transfer decrypted video to microcomputer, 205, and decoder, 203. Controller, 20, causes decoder, 203, to commence detecting SPAM information in the inputted video and waiting to receive header information and to cause microcomputer, 205, to transfer the video to monitor, 202M, causing monitor, 202M, to display the transmitted image.

At 8:30 PM, said program originating studio commences transmitting "Wall Street Weak," thereby causing the station to lurch in the fashion described in "One Combined Medium" and examples #1, #2, #3, and #4. The foregoing is presented by way of example, and modifications may be made in the structure of the various parts without functionally departing from the spirit of the invention. For example, decoders, 107, 224, and 231, may be conventional decoders that descramble analog television transmissions. The transmitted programming may be recorded at apparatus such as a properly configured video recorder rather than displayed at a monitor, 202M. Halter than a transmitter at a remote station, the source of the transmission may be a local video tape recorder or a laser disc player.

15 MONITORING RECEPTION AND OPERATION

Fig. 5 exemplifies one embodiment of a subscriber station configured and programmed to monitor. Fig. 5 shows a representative group of equipment which may other apparatus could be included. Associated with each intermediate and output apparatus is one or more appropriate decoders. A1 radio tuner & amplifier, 138, is radio decoder, 138, and other decoder, 281. A1 TV tuner, 215, is TV decoder, 212. A1 audio recorder/player, 205, is other decoder, 284. A1 video recorder/player, 217, is TV decoder, 218. A1 microcomputer, 205, is TV decoder, 203. All other tuner and/or recorder/player, 257, is other decoder, 283. A1 TV monitor, 202M, is TV decoder, 145. A1 multi-picture TV monitor, 148, are TV output systems, 149 and 150. A1 speaker system, 263, is other decoder, 227. All other decoder, 281, is other decoder, 227. All other output system, 251, is other decoder, 286. Each decoder is located physically inside the unit of its associated apparatus.

Any given SPAM decoder may merely monitor the operation of its associated apparatus or function also to control said apparatus in execution of SPAM controlled functions. In which case said decoder is preprogrammed to execute controlled functions). Fig. 5 shows each decoder as having capacity for transferring monitor information to signal processor, 200, by bus communications means. Said information is received and processed by processor, 200, by onboard controller, 14A, which controls communication of said bus means. Decoders, 138, 281, 282, 284, 218, 283, 145, 149, 150, 235, 227, and 286, merely monitor. Each one is located at a point in the circuitry of its associated apparatus where said one receives the information of the frequency, channel or transmission to which its associated apparatus is tuned. Each one is preprogrammed to detect and transfer via said bus means, the meter-monitor information of every unencrypted SPAM message in the transmission to which its associated apparatus is tuned. Decoder, 203, not only monitors its associated apparatus, microcomputer, 205, but also controls said apparatus. Onboard controller, 14A, controls the decoders that merely monitor. Decoders that execute SPAM controlled functions are controlled by controller, 20, of signal processor, 200. In Fig. 5, decoder, 203, is the only such decoder.

By embedding SPAM information in audio and video programming, conventionally recorded by recorders, these methods provide techniques for gathering statistics on what is recorded, for example, on video and audio cassette recorders and on how people reply such recordings. Video and audio tapes, videocassettes, compact discs, and "CD ROM" discs of data can contain unique codes, embedded in prerecorded programming, that identify usage of said programming when said tapes or discs are played.

AUTOMATING INTERMEDIATE TRANSMISSION STATIONS

Signal processing apparatus in Figs. 2, 2A, 2B, 2C, and 2D, and their variants automate transmission stations. The stations so automated range from wireless stations that transmit a single transmission to cable systems that cablecast many channels.

Fig. 6 illustrates a cable television head end that cablecasts several channels. The station receives programming transmissions by satellite antenna, 50, low noise amplifiers, 51 and 52, and TV receivers, 53, 54, 55, and 56. Microwave transmissions are received by antenna, 56 and 57, and television receivers, 58 and 59. TV broadcast transmissions are received by antenna, 50, and TV demodulator, 61. Other transmissions are received by other input means, 62. Each receiver/modulator/input apparatus, 53 through 52, transfers its received transmissions to a conventional matrix switch, 75, that outputs to one or more recorder/player, 76 and 78, and to apparatus that outputs transmissions over various multiplexing system, 92. When played on video recorders, 76 and 78, prerecorded programming can be transmitted via switch 75 to field distribution system, 93.

In the prior art, identification of incoming programming, however received, operation of video player and recorder equipment, 76 and 78, and maintenance of records are largely manual operations.

Fig. 6 shows signal processing apparatus to automate these and other operations. In the between each receiver/modulator/input apparatus, 53, 54, 55, 56, 57, 58, 59, 60, 61, or 62, and matrix switch, 75, is a dedicated distribution amplifier, 63, 64, 65, 66, 67, 68, 69, or 70, that splits each incoming feed into two paths. One path is the conventional path whereby programming flows from each receiver/modulator/input apparatus, 53, 54, 55, 56, 57, 58, 59, 60, 61, or 62, to matrix switch, 75. The other path inputs the transmission of said apparatus, 53, 54, 55, 56, 57, 58, 59, 60, 61, or 62, individually to signal processor system, 71.

At signal processor system, 71, which is a system as shown in Fig. 2D, the transmission of each apparatus, 53, 54, 55, 56, 57, 58, 59, 60, or 70, is inputted to a dedicated decoder (such as decoders, 27, 28, and 29 in Fig. 2D) that processes continuously the transmission of said amplifier, 63, 64, 65, 66, 67, 68, 69, or 70, selects SPAM messages in said transmission that are addressed to apparatus of said station, adds source mark information that identifies said encoded amplifier, 63, 64, 65, 66, 67, 68, 69, or 70, and transmits said decoded messages with said source mark information to code reader, 72. Signal processor system, 71, also has signal processor means to control system, 71, record code reader, 72, buffer, 8, and passes the information to cable program controller and computer, 73.

Cable program controller and computer, 73, is the central automatic control unit for the transmission station. Computer, 73, has an installed clock and is preprogrammed with information on the operating speeds and capacities of all station apparatus and the connection of said apparatus with matrix switch, 75. Computer, 73, has means for receiving input from local input, 74, and from remote stations via telephone or other data transfer network, 98. Such input include the complete programming schedule of the station with each unit of programming identified by its program unit identifier. Such input indicate when and how the station should receive each program unit, when and on which channel or channels and how the station should transmit the unit, what kind of programming the unit is--eg, conventional television, television/computer combined medium programming, etc.,--and how the station should process the programming. Computer, 73, is preprogrammed to receive and record schedule information and to maintain records which indicate the operating status of each controlled apparatus.

Computer, 73, monitors the operation of the station by means of TV decoders, 77, 79, 80, 84, and 88, each shown in detail in Fig. 2A. Computer, 73, has means to communicate control information with each decoder, 77, 79, 80, 84, and 88, to instruct each how to operate and how and where to search for SPAM information. Decoders, 80, 84, and 88, select and transfer SPAM meter-monitor information and by comparing said information to information of its controlled schedule records, computer, 73, can determine whether scheduled programming is being transmitted properly to field distribution system, 93, on each cable channel of the station. Whenever computer, 73, detects errors, computer, 73, can execute predetermined error correction procedures.

By means of the SPAM message information with source mark information received from code reader, 72, computer, 73, determines what specific program unit has been received by each receiver, 53 through 62, and is passing in line, via each distribution amplifier, 63 through 70, to matrix switch, 75. By comparing selected meter-monitor information of said message information with information of the programming schedule received from input, 74, and/or network, 98, computer, 73, can determine when and on what channel or channels the station should transmit the programming of each received program unit.

Computer, 73, has means for communicating control information with matrix switch, 75, and video recorders, 76 and 78, and can cause selected programming to be transmitted to field distribution system, 93, or recorded. Determining that incoming programming is scheduled for immediate retransmission can cause computer, 73, to cause matrix switch, 75, to configure its switches to transfer said programming to a scheduled output channel. Determining that incoming programming is scheduled for time delayed transmission can cause computer, 73, to cause recording of said programming. Determining that incoming programming is not scheduled for transmission can cause computer, 73, either to cause matrix switch, 75, to transfer the programming to no output of switch, 75, or to cause a selected recorder, 76 or 78, to cease recording; or both.

Computer, 73, has capacity for determining what programming is loaded on recorder, 76 and 78, and for positioning the start points (or other selected points) of program units at the play heads. Whenever programming is played on recorder, 76 or 78, decoder, 77 or 79 respectively, detects SPAM information embedded in the prerecorded programming played at the play heads of recorder, 76 or 78, and transmits said SPAM information to computer, 73. Said SPAM information can include not only program unit identification code information but also information regarding of the distance from the point on the tape at which a given SPAM message is embedded to the point where the program unit begins (or to any other selected point).

Computer, 73, has capacity for organizing units of programming bedded on recorder/player's to play according to a schedule and/or playing program units according to its station schedule. For example, computer, 73, causes recorder, 76, to move forward or rewind to the start of program unit, Y, causes recorder, 76, to rewind to the start of available space, and causes switch, 75, to configure its switches so as to transfer the output of recorder, 78, to the input of recorder, 76. Computer, 73, causes recorder, 78, to play and recorder, 76, to record for the duration of program unit, Y. Computer, 73, causes recorder, 78, to move forward or rewind to the start of program unit D and causes recorder, 78,

to play and recorder, 76, to record for the duration of program until D. Finally computer, 73, alters its contained records to document the locations of Y, Z or O on the tape or recorder, 78, and the availability of the spaces that Y and D occupy on the tape or recorder, 78, or recording other programming.

In the preferred embodiment, at least two signal processors (such as the signal processor of said system, 71, and primary processor, 85) monitor the transmissions of any given transmission station,

EXAMPLE #8

Using the capacity described above for identifying, selecting, and recording received programming, for organizing recorded programming to play according to schedule, for playing selected organized programming on schedule, and for retaining, recording, and retransmitting monitor records that document the transmission of program units, a remote distribution station can transmit to a plurality of intermediate transmission stations programming that is scheduled for delayed transmission, cause each station to select and retransmit programming according to its schedule, and cause signal processing apparatus to transmit to remote auditing stations signal records that document the transmission of specific program units at the specific stations of said plurality. For example, a so-called "spot tap" agency that sells "the spot time" of local broadcast stations and cable systems can transmit spot commercials and cause each station

In example #8, a remote distribution station transmits television programming to a plurality of intermediate stations by a satellite. Among the intermediate stations are broadcast stations in Texas and Washington, and the station at Fig. 6 in Vermont. Each intermediate station is programmed to process messages transmitted from said remote distribution station.

At 5 P.M., said remote distribution station commences contacting, individually and in turn, the computers, 73, of each intermediate station, via network, 88, and input schedule information to each computer, 73. The information identifies the time and satellite transponder said stations should select and record, and when and on which channel said computer, 73, should cause the station to transmit the units. For the station of Fig. 6, said remote distribution station informs computer, 73, to select and record program units Q, D, Y, and W, to transmit Q at 2:30 PM on the channel transmitting "USA Cable News Network," to transmit W at 2:45 PM on Cable News Network, to transmit Y at 2:45:00 PM on the channel transmitting "USA, Cable News Network" in inputting schedule information.

At 3:50 A.M., the schedule information causes sal 1 to receive the transmission of all intermediate stations, each, to receive its antenna to receive Galaxy transporto 23 of the Galaxy satellite. Computer 73, instructs earth station, 50, to move its antenna to receive Galaxy and instructs amplifier, 51, and receiver, 53, to receive the transmission of transporto 23. (Means what's up computer, 50, exists to record, 76, to move its antenna to receive Galaxy transporto 23 of the Galaxy satellite, 53, and receiver, 51, to receive the transmission of transporto 23.) Computer 73, causes transmitter 55, to transfer transmissions from receiver, 53, to recorder, 76, causes recorder, 76, to move its antenna to receive Galaxy transporto 23 of the Galaxy satellite, 53, and receiver, 51, to receive the transmission of transporto 23. Computer 73, causes sal 1 to move its antenna to receive Galaxy transporto 23 of the Galaxy satellite, 53, and receiver, 51, to receive the transmission of transporto 23. Computer 73, causes recorder, 76, to move forward or rewind to a particular place on the tape located at its record head.

Receiving of the select-Q-message (#8) causes computer 73, to determine that the "program unit identification code" information of unit Q matches schedule information which causes said computer, 73, to cause a recorder, 76, to record program unit Q.

Each computer, 73, is programmed to account for and keep track of the quantity of time available for additional recording on the individual tapes based on the records (9g., 76 and 78) of its station, and receiving a cue-to-select message can cause a computer, 73, to cause its station to switch from a primary to a secondary recorder.

Where a computer, 73, causes a recorder (e.g., 76 or 78) station to cease recording, said computer, 73, checks its contained recorder in a predetermined fashion to determine whether all scheduled times have been received. Whenever a computer, 73, determines that no further units will be received, said computer, 73, causes its station to cease receiving the transmission of said remote distribution station, and commences automatically organizing, in the fashions described

63 Said message causes the station of Fla. 6 to cease transmitting the Cable News Network to said system, 93, and

Causing the station to transmit unit Q causes a signal processor of system 71, and signal processor 96, to retain master-monitor information or unit Q, to record signal record information of prior programming-i.e., Cable News Network-and may cause one or both of said processors to transmit signal record information or one or more remote control master-monitor information or unit Q.

אנו מודים לך על תרומותך ותרומותך יונתנו בברכה

- The station has capacity to process and transmit combined medium programming. Fig. 6 shows signal strippers, 81, 85, and 89, well known in the art, that computer, 73, can cause to remove SPAM information from programming, 82 and signal generators, 82, 86, and 90, well known in the art, that computer, 73, can cause to embed SPAM information, 83 Said generators, 82, 86, and 90, have capability for receiving control information and programming in a transmission 84 from computer, 73, and distinguishing said information from said programming.

For example, computer, 73, must insert locally generated instruction sets into a local transmission. Program unit 85 Q is a commercial that describes coupon specials at local supermarkets. The formulas that apply to discounts and the items on special vary, and the information embedded must relate the formulas and items that apply 86 at local supermarkets at the time of transmission.

Computer, 73, is preprogrammed to process combined medium programming. When the remote station inputs 87 information via network, 96, regarding unit Q, said station instructs computer, 73, to commence generation at a time interval prior to the scheduled playing of Q. Such a time period is called "interval," as in "interval C" or unit Q. Prior to 88 generation time, local-formula-and-item information is inputted to computer, 74, or network, 96.

Said information may be inputted from local input, 74, or network, 96.

An instance of instructions that cause a computer to generate a program instruction set is an "immediate generation set." In the preferred embodiment, an intermediate generation set is prerecorded in a program unit with conventional programming whose program set generation said immediate set causes. Said intermediate set is pre-recorded before the start of said conventional programming. An intermediate set contains generally applicable information 89 of the program instruction set where a generation it causes. For example, the intermediate set of Q, includes information of an announcer saying, "Ten-three", "Ten-five" and "Hot version Click." Said generally applicable information lacks specific information that is required to complete the generation of a given instance of a generated program instruction set. (For example, in the case of unit Q, the intermediate generation set lacks information of the particular discount formula and items offered as coupon specials at the scheduled time of the transmission of unit Q at the particular 90 supermarket or market that are local to the station of Fig. 6.) When executed at a computer, 73, that is preprogrammed with local-formula-and-item information, the instructions of a intermediate generation set cause said computer, 73, to generate local-formula-and-item-or-time-of-transmission information, thereby generating the program instruction set applicable 91 to a particular transmission at a particular intermediate station. The set so generated may consist of computer program instructions and/or data.

Example 19 focuses on generating, embedding, and transmitting program instruction set programming of unit Q.

At interval Q time prior to the scheduled playing of Q, instructions cause computer, 72, to commence generation. Computer, 73, causes matrix switch, 75, to switch the input from recorder, 76, to no output; recorder, 76, to position the start of unit Q at play head decoder, 77, to commence detecting signals on all lines of the full video frame; then recorder, 76, to commence playing which causes decode, 77, to detect a message. Said message is addressed to ITR computer, 73, and contains an information segment whose information is the intermediate generation set of Q.

Detecting said message causes decoder, 77, to transmit said message to computer, 73. Racking said message at computer, 73, and not distinguishing from computer, 73, (analogous to SPAM-controller, 205C, at microcomputer, 205) to execute control functions. Computer, 73, is caused to load said intermediate set at RAM then position the start of the unit Q conventional television programming at the play head of recorder, 76, and execute said set as a machine language job.

Said set causes computer, 73, to compute formula-and-item-or-time-of-transmission information. Said information consists of both computer program instructions and data. Data in said local-formula-and-item information includes, for 92 example, the street address of every supermarket in the locality said station. Other formula-and-item information can

be computer program instructions. For example, one discount special is unrimmed pork bellies advertised in conventional television programming unit Q. The offer is, "Discount Supermarkets will deliver to You, at cost, all the pork you need ...". The cost of delivery involves transportation from the central warehouse to each subscriber who orders a pork belly. The cost of delivery for any given subscriber is calculated under control of formulae that are computer program instructions.

The particular of the pork belly special illustrate generating formulas-and-item-of-this-transmission information. The cost of a pork belly for any given subscriber is computed according to a formula:

$$(1) \quad Y = B + b + c(X)$$

where:

- Y is the delivered cost to said subscriber,
- a is the supermarket's cost per pork belly at a warehouse,
- b is the cost of transportation to the market,
- c is the cost per mile of delivery from said market, and
- X is the distance between said market and said subscriber.

Pork belly prices vary from day to day. Transportation costs vary from time to time and place to place. Each time the programming of unit Q is transmitted to subscribers, the values of b and c are computed according to the following equations (2) and (3) respectively:

$$(2) \quad b = (p * q + d)Z$$

where:

- p is the cost of gasoline per pork belly unit mile between warehouse and market,
- q is the wage of the driver per unit mile,
- d is the depreciation of the vehicle per unit mile and
- Z is the distance in miles between warehouse and market.

$$(3) \quad c = r + s + dd$$

where:

- r is the cost of gasoline per unit mile between market and subscriber,
- s is the wage of the local driver per unit mile, and
- dd is the depreciation of the local vehicle per unit mile.

For any transmission of Q, the following variables are data pre-entered into computer, 73, and recorded in said local-formulas-and-items information: a, p, q, c, Z, r, s, and dd.

When computer, 73, commences generating, the local-formulas-and-items information includes information that:

- a is 1000.00
- p is .00825
- q is 12
- d is .1
- Z is 275
- r is .007
- s is 2.00
- dd is .11

The intermediate generation set includes instructions to compute values of variables b and c according to formulas (2) and (3). Computer, 73, selects information of a, p, q, c, Z, r, s, and dd; computes the value of b, to be 62.1875; computes c to be 2.117; and replaces variable values, a, b, and c, in a higher language line of program code that is

among the generally applicable information of said program instruction set and is:

$$Y = a + b + (c * X)$$

to become formulae-and-item-of-this-transmission information of:

$$Y = 1000.00 + 62.1875 + (2.117 * X)$$

- 10 Computer, 73, selects and computes other variables and replaces other variable values until a complete instance of higher language code has been generated and exists at memory. Computer, 73, compiles, links, generates a PRO-GRAM, EXE file that is said program instruction set; and places said file at a particular program-set-to-transmit memory of computer, 73. The program instruction set generated in example 19 is called the "program instruction set of Q". Said intermediate set causes computer, 73, also to generate a data module called a "data module set". Computer, 73, selects, from said local-formulas-and-items information, information of the street address of every supermarket in the vicinity and the order-taking telephone number 1-(600) 247-8700. Computer, 73, places selected information in a file called DATA OF ITS until said file constitutes the "data module set of C".
- 15 Subsequently, at the scheduled time of playing Q, the station is transmitting a network transmission. At the program originating studio, a SPAM message to ITS computers, 73, is transmitted. The decoder of signal processing system, 71, that receives the transmission of distribution amplifier, 62, detects said message and inputs said message with source mark information to computer, 73. Said message and mark cause computer, 73, to cause recorder, 76, to commence playing and matrix switch, 75, to transfer the output of recorder, 76, to modulation, 83, which causes transmission of unit Q to field distribution system, 93. In addition, the playing schedule causes generator, 82, to cause command playing other signal information in the normal transmission location (for example, telephone) and transmit a SPAM and of file signal.
- 20 Immediately recorder, 76, transmits three SPAM messages embedded in the programming of Q. The first is the align-URS-microcomputer-205 message (#9); the second message is embedded in a distance after said first that is sufficient to allow time for subscriber signals to combine. Said second is the "Sync-SPAM"-recognition message (#9).
- 25 The third is the control-invoking message (#9). Causing recorder, 76, to play cause decoder, 77, to detect a series of SPAM messages that are embedded in Q and addressed to ITS computers, 73.
- 30 The first message contains execution and meter-monitor segments. Said message causes computer, 73, to generate and transmit the data-module-set message (#9). Computer, 73, causes generator, 82, to commence embedding information received from computer, 73, normal transmission location; causes generator, 82, to stop all signals from the 35 segments information of said meter-monitor segment, adds information that identifies the station of Fig. 6 and the time of transmission, and retains the modified meter-monitor information; and transmits to generator, 82, complete information of said message. Computer, 73, transmits a "01" header, a SPAM execution segment addressed to URS-microcomputers, 205; said retained meter-monitor information, any required padding bits, complete information of said data file, DATA_OFITS, and a SPAM end of file signal. Receiving said message causes generator, 82, to transmit said message to said system, 93.
- 40 The second message in the series causes computer, 73, to generate a second message that includes said program instruction set of Q and to cause said message to be transmitted in the transmission of the programming of Q and transmitted to field distribution system, 93. Said message is the "program-instruction-set message (#9)." Automatically, computer, 73, selects the information of a meter-monitor segment, adds information that identifies the station of Fig 6 and the time of transmission, modifies the meter-monitor segment field information to relocate said added information, and retains the received, added and modified meter-monitor information. Automatically, computer, 73, selects and transmits to generator, 82, a "01" header, a SPAM execution segment addressed to URS microcomputers, 205; said retained meter-monitor information; complete information of the file at the program-set-to-transmit memory of computer, 73, that is said program instruction-set message (#9).
- 45 Receiving said information causes generator, 82, to embed said information in the normal transmission location of the programming of Q transmission being transmitted via generator, 82, to field distribution system, 93; thereby transmitting said program-instruction-set message (#9) to said system, 93.
- 50 The third message causes computer, 73, to cause skipping and generator, 82, to cease embedding.
- 55 Subsequently, as recorder, 76, plays, recorder, 76, transmits eight SPAM messages embedded in the programmed programming of Q. Said messages include the 1st commence-outputting message (#9) and the "1st cause" outputting

message (#9).

At the scheduled end time of playing Q, a message is embedded at said program originating studio and transmitted in said network. Said message and mark information causes computer, 73, to cue said network transmission and continue in its automatic playing fashion. Computer, 73, causes matrix switch, 75, to cease transferring the output of recorder, 76, to modulator, 93, and commence transferring input from distribution amplifier, 63, to modulator, 93, which causes said network transmission to field distribution system, 93. Automatically, computer, 73, may cause generator, 82, to embed the "databand-URS-microcomputers-205" message (#9) that causes subcarrier stations whose microcomputers, 205, are combined to the computer system of recorder, 76, to commence embedding other signal information, according to the schedule, computer, 73, may cause generator, 82, to commence embedding other signal information, (for example, intertext). Computer, 73, causes recorder, 76, to cease playing and to prepare to play its next scheduled program unit.

NETWORK CONTROL... EXAMPLE #10

In example #10, a program originating studio transmits the commercial of program unit Q in a network transmission and controls a plurality of intermediate transmission stations each of which controls, in turn, a plurality of ultimate receiver stations. The station of Fig. 6 is one intermediate station. The station of Fig. 6 receives said network transmission at receiver, 53, and retransmits said transmission immediately via modulator, 83. The program unit Q of example #10 is identical to unit Q of example #9, and each intermediate station must transmit its own program instruction set.

Prior to an early time, complete local-and-item information is inputted to the computer, 73, of each intermediate transmission station. At the station of Fig. 6, the local-formula-and-item information in example #10 is identical to example #9. (At a second intermediate station, the local-formula-and-item information includes A = 1000.00, p is .00625, q is .1, r is .11, s is .537, t is .0062, u is 1.98, and dd is .10.)

At said early time, the computers, 73, of said controlled intermediate stations are caused to receive a transmission. Schedule information causes said computers, 73, to cause their earth station receivers, 50, amplifiers, 51, and TV receivers, 53, to turn to a particular satellite transmission. Those controlled decoders of the signal processor systems, 71, of said stations that process the transmission of distributed amplifiers, 63, detect and input SPAM information to the computers, 73.

Then the program originating studio transmits a SPAM message that is addressed to ITS computers, 73 and controls information segment, information of the aforementioned intermediate generation message (#10). Said dedicated decoders detect and input said

message to the computers, 73. Said message is called the "generate-set-information message (#10)." Said dedicated decoders detect and input said

message to the computers, 73. Said message causes each computer, 73, to load said intermediate generation set at RAM; execute the information complete program instruction set information of this instance of Q, and record said information at memory. The set generated at the station of Fig. 6 in example #10 is the "program instruction set of Q1".

At the station of Fig. 6, said intermediate generation set causes the computer, 73, to record the computed, compiled, and linked program instruction set of Q in a file named "PROGRAM.EXE" on a computer memory disk of computer, 73. Executing said intermediate generation set also causes said computer, 73, to select data among the local-formula-and-item information of said station, including "Nabisco Zweiback Feeding Roast" and the street address of markets in the vicinity of the station of Fig. 6, and to record said selected data on said memory disk in a data file named DATA OFITS. In so doing, said computer, 73, generates said data module set of Q1. (At said second station, said intermediate set causes the computer, 73, to compute formula-and-item-of-this-transmission information of:

$$Y = 1000.00 + 132.2362 + (2.0882 \cdot X)$$

The set generated at said second station is the "program instruction set of Q2".

One difference between example #9 and example #10, which is based on the preprogrammed schedule information to be recorded at non-volatile disk memory,) is that the generate-set-information message (#10) causes the generated program instruction set and data module

transmits a second SPAM message called the "load-set-information message (#10). Said message causes computer, 73, to load PROGRAM.EXE and DATA_OFITS at program-set-to-transmit; and data-set-to-transmit RAM memories of computer, 73.

Then said program originating studio alerts to transmit the conventional television programming of unit Q. After an interval said studio embeds and transmits a SPAM message addressed to ITS computers, 73, called the

"transmit-data-module-set message (#10)." Receiving said transmit-data-module-set message (#10) causes computer, 73, to generate a first outbound SPAM message that includes the data file, DATA_OFITS, at its data-set-to-transmit RAM memory, and to cause said message to be transmitted to its field distribution system, 93. The first outbound SPAM message is called "data-module-set message (#10)." At the station of Fig. 6, computer, 73, selects the meter-monitor segment of said transmit-data-module-set message (#10), adds information that identifies the station of Fig. 6 and the time of transmission; modifies the meter-monitor formal field information to reflect said added information; and transmits the received, added, and modified meter-monitor information. Then said computer, 73, selects and transmits to generator, 82, a "01" header; particular SPAM execution segment that is addressed to UFR microcomputers, 205, said retained meter-monitor information; any required padding bits; complete information of the data file at the data-set-to-transmit RAM memory which is said file, DATA_OFITS, and is said data module set of Q1; and information of a SPAM end of file digital.

Receiving the data-module-set message (#10) causes generator, 82, to embed said information in the normal transmission location of the programming of Q being transmitted via said generator, 82, to field distribution system, 93, thereby transmitting the data-module-set message (#10) to said system, 93.

Then said program originating studio transmits a SPAM message that is addressed to ITS computers, 73, and that contains executive and meter-monitor segments. (Said message is called the "transmit-and-execute-program-instruction-set message (#10).")

Receiving said message causes each of said computers, 73, to generate a second outbound SPAM message that includes information of the program instruction set at its program-set-to-transmit RAM memory and to cause said message to be transmitted to its field distribution system, 93. (Hereinafter, the outbound SPAM message is the "program-instruction-set-message (#10)." The station of Fig. 6 transmits the program instruction set of Q1 and a second intermediate station transmits the program instruction set of Q2.)

Example #10 is discussed more fully below.

So far this disclosure has described an intermediate transmission station transmitting television. The station could process and transmit radio programming in the same fashions. Likewise, the station could transmit broadcast print and data communications. Intermediate transmission station apparatus can include signal processing regulating system apparatus as in Fig. 4 by means of which transmission are decoupled and metered, apparatus that encrypt program transmissions selectively and monitoring system apparatus in the spirit of Fig. 5.

AUTOMATING ULTIMATE RECEIVER STATIONS

Signal processing apparatus automate ultimate receiver stations. Fig. 7 exemplifies one embodiment of an ultimate receiver station; in field distribution system, 93, of Fig. 6, and may be a home, office, theater, hotel, or any other station where programming is displayed.

Fig. 7 shows apparatus for inputting programming (including SPAM information selectively), intermediate apparatus (for processing and/or recording selectively), output apparatus (for displaying programming selectively); other controlled apparatus; and other meter apparatus. Input apparatus include satellite earth station, 250; satellite receiver circuitry, 251; converter boxes, 201 and 222; antennas, 258 and 259; and other input apparatus (for example, a laser disc player). Said apparatus input their information to matrix switch, 258, which is a conventional matrix switch. Intermediate apparatus include microcomputer, 205; television recorder/player, 217; audio recorder/player, 255; computer memory unit, 256 (for example, a fixed disk), decoder, 224, display, 231, signal stripper, 229, signal generator, 230, and other intermediate apparatus, 257, for example, amplifier apparatus. In addition, the tuner of TV set, 202--that is, TV tuner, 215--which is not distinguished from monitor, 202/M, in Fig. 7, and the tuner/amplifier of radio, 209--that is, radio tuner & amplifier, 213--which is not distinguished from radio, 209, in Fig. 7, are also intermediate apparatus. All intermediate apparatus receive their programming input from and transmit their programming outputs to matrix switch, 258. Output apparatus include, TV monitor apparatus of TV set, 202; printer, 221; speaker system, 263, and one or more other output systems, 261. All output apparatus receive their programming input from matrix switch, 258. Other controlled apparatus include electronically actuated window opening and closing means, 208; furnace, 206; air conditioning system, 207; and other controlled apparatus, 260. Other meter apparatus include an electronically actuated utilities meter, 262.

One or more SPAM decoders exist at each apparatus controlled by SPAM message information. Appropriate decoders exist at microcomputer, 205, at recorder/player, 217 and 255, (which can operate in fashion of the station of Fig. 6) at radio, 209, and TV set, 202, (which radio and TV set can be actuated, turned, and controlled in other function(s) and at computer memory unit, 256; other intermediate apparatus, 257; printer, 221; speaker system, 263, and other output means, 261. (For simplicity, Fig. 7 does not distinguish said decoders.)

Two matrix switches, 258 and 259, communicate programming and SPAM message/control information transmissions among station apparatus. Switch, 258, is a conventional matrix switch with capacity for switching television, radio, and other electronically transmitted programming. Matrix switch, 259, is a digital matrix switch with capacity for switching and other electronically transmitted programming. Matrix switch, 259, is a digital matrix switch with capacity for switching

binary information transmissions. By means of matrix switch, 259, all apparatus communicate control information and SPAM message that have been detected in programming transmissions.

For communicating switch request information to the controller, 20, of signal processor, 200, said decoders have separate control information bus means (not shown in FIG. 7). A processor, 20A, that is located at controller, 20, separate from the CPU and controlled by said CPU controls communications of said bus means.

Signal processor, 200, is the basic SPAM control apparatus of the station. Signal processor, 200, communicates a control information directly with decoders, 224 and 231, signal stripper, 229, signal generator, 230, microcomputer, 205, and matrix switch, 259. Via matrix switch, 259, a signal processor, 200, has means for communicating control information individually to all controlled apparatus. The aforementioned SPAM decoders have capacity for communicating with each other by means of matrix switch, 259. Signal processor, 200, controls matrix switches, 258 and 259. Microcomputer, 205, controls apparatus of the station in accordance with preprogrammed instructions of the subscriber. Microcomputer, 205, has capacity to communicate control information (under control of signal processor, 200) with selected apparatus by means of matrix switch, 259.

(This is a representative group of equipment; many other apparatus could be included in FIG. 7.)

MORE REGARDING THE PREFERRED CONTROLLER OF A SPAM DECODER

The controller, 39, 44, or 47, of a SPAM decoder has capacity for communicating information from the matrix switch, 39; to matrix switch, 259, and for receiving information from matrix switch, 259, at the decoder, 39K, buffer, 39G, and control processor, 39J. Said control processor, 39J, has capacity to communicate switch request information to signal processor, 200, via the aforementioned control information bus means and has SPAM-switch-connection register memory.

COORDINATING A SIMULCAST

FIG. 7B illustrates control of a stereo simulcast.

Turning on or changing a channel at a receiver causes apparatus at said receiver to transmit an interrupt signal of new-channel information and input said signal to the control processor of the decoder associated with said receiver [which said apparatus has means of input].

A subscriber decides to watch a television program which is stereo simulcast on a radio station. Switching power on and tuning causes tuner, 215, to input an interrupt signal of new-channel information to control processor, 39J, of decoder, 203. Said signal causes said processor, 39J, to cause EOF's valve, 39F, to commence processing information (thereby discarding any end of file signal information); to cause EOF's valve, 39F, to commence processing for an end of file signal; and to cause decoder, 203, to commence receiving television. In due course, the program originating studio sends an end of file signal.

Periodically said studio sends and transmits a Tune-Radio-to-FM-104.1 message that consists of a '01' header, an execution segment of particular activate-simulcast information that is addressed to URS radio decoders, 210, a master-monitor segment that contains the "program unit identification code" information of said particular television program, an information segment that contains particular 104.1-MHz information, and an end of file signal.

Receiving said message causes controller, 39, to transfer said message to the radio decoder, 210, of radio, 209. Controller, 39, compares programmed 10-21 information to the information in its SPAM switch-connection register memory. Not resulting in a match causes controller, 39, to input a switch-203-to-210 instruction to control processor, 20A, via the control information bus means. Said instruction causes control processor, 20A, to establish a transmission link between the controller, 39, or decoder, 203, and the controller, 44, of radio decoder, 209. Controller, 39, matrix switch, 258, to switch and to transfer a 10-210 instruction to controller, 39. Receiving said instruction causes controller, 39, to place 10-210 information at said SPAM-switch-connection memory, then to transfer said message to the controller, 44, of said decoder, 210.

Said message causes said controller, 44, switch power on to and tune radio, 209, to the frequency, 104.1 MHz. Because the station of FIG. 7 (and FIG. 7B) is programmed to collect monitor information, said message also causes transmission of monitor information to signal processor, 200. Decoder, 203, transmits via bus means a first information transmission of the execution and master-monitor information of said message with first source mark information that identifies TV set, 202. Decoder, 210, transfers a second information transmission of the execution and master-monitor information of said message with source mark information identifying radio, 209. Said first transmission causes onboard controller, 14A, to initiate a first signal record, associated with source mark information of TV set, 202, that is based on the program unit identification code. Said second transmission causes onboard controller, 14A, to initiate a second signal record, associated with source mark information of radio, 209, based on said program unit identification code. In a predetermined fashion onboard controller, 14A, determines that TV set, 202/decoder, 203, is the principal source of information associated with said code; retains information in said second record that identifies

said second record as a secondary record of said first record; and retains information at said first signal record that identifies radio, 209/decoder, 210, as a secondary source, in so doing, onboard controller, 14A, consolidates signal record information of transmissions that contain different source mark information but common program unit identification information.

Switching power on to said radio, 209, and tuning radio, 209, causes decoder, 210, to commence processing SPAM message information in said frequency. Radio, 209, inputs an interrupt signal of low-frequency input information to the control processor, 44J, of the controller, 44, of radio decoder, 210 (which does not include radio receiver circuitry, 41, because the input is the transmission received by the circuitry of radio, 209.)

The program originating studio that originates the transmission of said frequency periodically embeds and transmits an Activate-Stereo-Output SPAM message that consists of a '01' header, an execution segment of activate-speakers information that is addressed to URS signal processor, 200, a master-monitor segment that contains second program unit identification code information of the audio program unit of said radio transmission and primary program unit information transmission link between said controller, 44, and said controller, 20. Said message causes controller, 20, to determine that certain preconditions are met—more precisely, that TV set, 202, and radio, 209, are tuned, respectively, to the television channel and radio frequency of the stereo simulcast. Automatically, controller, 20, executes station-specific-simulcast instructions.

Station-specific-simulcast instructions reflect the particular fashion in which the subscriber of any given station wishes to have audio of stereo simulcast outputted at his station, and preprogrammed station-specific-simulcast instructions vary from subscriber station to subscriber station. The station-specific-simulcast instructions of the station of FIGS. 7 and 7C, cause said station to emit the audio of said transmission in a particular fashion. TV set, 202, and of radio, 209, cause emitting sound. Matrix switch, 258, switches to input from radio, 209, to speaker system, 203. Controller, 20, causes speaker system, 203, to switch power on and commence operating. (At other stations, certain programs may not be satisfied—for example, the TV set, 202, may be tuned to a channel other than channel 13. Said stations would not execute station-specific-simulcast instructions. At stations where station-specific-simulcast instructions are executed, the instructions vary and cause different functioning at different stations. For example, balance and volume can vary from station to station.)

Automatically, monitor information is collected at signal processor, 200, that reflects the operation of speaker 9V. Item, 263, Onboard controller, 14A, initiates a third signal record, associated with source mark information of speaker system, 263, and consolidates signal record information of three different monitor information transmissions that contain different source mark information but common program unit identification information.

RECEIVING SELECTED PROGRAMMING

FIG. 7C illustrates monitoring multiple channels and receiving selected programming. The station is preprogrammed to hold records of stocks and receive news about said stocks. At control processor, 35J, of decoder, 30, with news-of-interest information that includes "T".

Remote stations broadcast print transmissions. Remote service-A station transmits an AT&T news item in a message that contains subject matter information of a Select-AT&T message then to transmit an AT&T News message. Said Select-AT&T message contains "T". Receiving said message causes the station of FIG. 6 to transmit a number of times digital data channel A Select-AT&T message then to transmit an AT&T News message. Said Select-AT&T message contains "T". Said AT&T News message contains said AT&T News item.

Signal processor, 200, scans all channels in the fashion of example #5, in due course, one Select-AT&T message is detected at decoder, 30, and inputted to the controller, 39. Receiving said message causes controller, 39, to detect message, 39G, said message to the controller, 20, of signal processor, 200, with channel mark information. Receiving said message causes controller, 20, to cause converter box, 222, to receive the transmission signalled by said channel mark; to cause All signal decoder, 250, (which is identical to the TV signal decoder of FIG. 2A with added capacity of the radio signal decoder of FIG. 2B plus the other signal decoder of FIG. 2C) to commence processing detected SPAM information; and to establish a transmission link between box, 222, and decoder, 200.

In due course, said AT&T News message is transmitted on channel A and input to controller, 39, of decoder, 200. Receiving said message causes controller, 39, to cause microcomputer, 205, to process said message. Automatically, controller, 39, executes the instructions of a particular preprogrammed controlled function and inputs to an input buffer of microcomputer, 205, said AT&T news item. Microcomputer, 205, causes controller, 20, to switch the input from microcomputer, 205, to printer, 221, and causes printer, 221, to print said AT&T news item.

MORE ON EXAMPLE #7 ... COMBINING TO THE COMPUTER SYSTEM SELECTED

In the present invention, the computer information of any given combined medium combining is processed by a

computer system that consists of a plurality of computers, each at a subscriber station, all processing in parallel under control of one input at a program originating studio. The present invention includes capability whereby a program originating studio can cause selected computers to combine to the computer system of said studio.

Microcomputers, 205, of a plurality of subscriber stations with program-of-interest information programmed with program-of-interest information includes information of station-specific-selection-and-display instructions. Said program-of-interest information includes information of television programs that subscribers wish to view. Some are combined medium programs. Said station-specific-selection-and-display instructions reflect the specific fashion in which any selected program is to be selected and displayed.

The program-of-interest information at microcomputer, 205, or the station of Figs. 7 and 1C includes specific-WSW information that reflects the wish of the subscriber to view "Wall Street Week". The station-specific-selection-and-display instructions include information that said subscriber will pay up twenty-five cents to receive said program and that, if the TV set, 202, is switched off when said program is received, power should be switched on to said TV set, 202, and said program should be displayed at monitor, 203M, and, in addition, said program should be recorded at said recorder/player, 217.

The computer, 73, of each intermediate station is programmed with schedule information that reflects the time and channel on which said station will retransmit "Wall Street Week". The information of computer, 73, of the station Fig. 6 is CC13 and particular-8-30. (Another computer, 73, is programmed with CC11 and particular-9-30.) The program originating studio transmits a Prepare-To-Referent message of information segment and specific-WSW information that includes generally applicable enable-WSW-on-XXXX-al-YYYYYYYYYY information and specific-WSW information, timing instructions and encrypt-audio instructions.

Receiving said message causes the station of Fig. 6 to input the information segment to computer, 73, and execute the input. (Other stations function similarly.) Said instructions cause said computer, 73, to generate enable-WSW-on-CC13-al-particular-8-30 information and a Select-WSW-Program message and retain said message in memory. Computer, 72, generates said information by replacing variables, XXXX and YYYYYYYYYY, in said enable-WSW-on-XXXX-al-YYYYYYYYYY information with said CC13 and said particular-8-30 information. (Said instructions cause said another 73, to generate enable-WSW-on-CC11-al-particular-9-30 information.) Said instructions cause computer, 72, to generate a Specific-WSW-Enabling-message, which is the above-noted local-enabling message (#7), and to retain said message at memory.

Said limiting instructions cause each intermediate station to commence transmitting its Select-WSW-Program message after a particular enabling time. In due course, said timing instructions cause computer, 73, to commence transmitting its Select-WSW-Program message in the normal transmission location of cable channel 13. Subsequently said instructions cause computer, 73, to receive the transmission of the program originating studio of "Wall Street Week"; input said transmission, via matrix switch, 75, to apparatus that encrypts the audio portion of said transmission; cause said apparatus to encrypt; and transfer the output of said apparatus, via matrix switch, 75, to field distribution system, 93, via the modulator, 82, 86, or 90, or cable channel 13.

Signal processor, 200, of the station of Fig. 7 detects one Select-WSW-Program message. Receiving said message causes a signal processor, 200, to input said message to microcomputer, 205. Said message causes microcomputer, 205, to input said enable-WSW-on-CC13-al-particular-8-30 information to the controller, 20, of signal processor, 200.

Then said limiting instructions cause said computer, 73, to transmit said local-enabling-message (#7), of example #7.

(Simultaneously other subscriber stations [i.e., ultimate receiver stations] of field distribution systems, 93, of other intermediate transmission stations, each receive the station specific SPAM messages of their specific intermediate stations, tune to an intermediate station specific channel [log, cable channel 11 rather than 3] in an intermediate station specific fashion [e.g., by decrypting with cipher key Tar rather than Ca] and oven at an intermediate station specific time [e.g., at 9:30 PM rather than 8:30 PM] to receive "Wall Street Week".) Sample selected subscriber station specific SPAM information in their subscriber station specific fashions, determine whether unauthorized tampering has occurred, and respond station specifically in fashions described above.)

Up to a point, the station of Fig. 7 functions just as the station of Fig. 4 in example #7 to function. Said point occurs after controller, 20, executes his additional 2nd-stage-enable-WSW-program instructions which, at the station of Fig. 4, cause apparatus to commence transferring decrypted television "Wall Street Week" to microcomputer, 205, and monitor, 202M.

At the station of Fig. 4, the television output of the PC Microkey System of microcomputer, 205, is inputted directly to TV monitor, 202M. By contrast, at the station of Fig. 7, the television output of microcomputer, 205, is inputted to matrix switch, 258. Furthermore, the station of Fig. 7 is programmed with the aforementioned station-specific-selection-and-display instructions.

At the station of Fig. 7, said additional 2nd-stage-enable-WSW-program instructions causes controller, 20, to cause

said station to determine that monitor, 202M, is not on and operating. Decoder, 145, responds by transmitting 202M-is-not-on information to controller, 20. Said 202M-is-not-on information causes controller, 20, under control of said additional 2nd-stage-enable-WSW-program instructions, to cause microcomputer, 205, to process the station-specific-selection-and-display instructions. Microcomputer, 205, inputs to controller, 20, to instruct decoder, 145, to switch power on to monitor, 202M, and tune monitor, 202M, cause matrix switch, 258, to transfer decrypted audio from decoder, 107, to monitor, 202M, and also to recorder/player, 217, cause matrix switch, 258, to transfer video from microcomputer, 205, to monitor, 202M, and also to recorder/player, 217, cause matrix switch, 258, with TV signal decoder, 218, at recorder/player, 217, that controls recorder/player, 217, and cause said decoder, 218, to switch power on to recorder/player, 217, and cause recorder/player, 217, to record the inputted audio and video.

CONTROLLING COMPUTER-BASED COMBINED MEDIA

15 The process of controlling computer-based combined media is continuous and involves systematic inputting and maintaining of up-to-date user data at each subscriber station. For example, only at subscriber stations where stock data is up-to-date can the first message of "Wall Street Week" generate Fig. 1A. Images that actually show the performance of portfolios of subscribers.

The present invention provides means and methods for inputting and maintaining data at subscriber stations. Microcomputer, 205, has an installed modem; receives information transmitted by means of telephone or data network, 262; and is programmed to process data received via said network, 262. Each time the subscriber who represents a subscriber buys or sells stocks for said subscriber, a computer at said broker's station telephones microcomputer, 205, to update its portfolio records, and causes microcomputer, 205, to update its portfolio records. Each weekday a remote stock-data station transmits all closing stock price data applicable that day and causes each subscriber station to select and record at the microcomputer, 205, of said station the closing price datum or data that apply to the stock or stocks of the portfolio of said computer. Said remote station transmits said closing stock price data and causes specific subscriber stations to select and process their specific information of interest in the fashion in which remote news-service A station transmits the AT&T news item and caused selected stations to select and process said item.) Alternatively, a station transmitter in the AT&T news item and caused selected stations to select and process said item automatically. A remote data station transmits the AT&T news item and example #4 commences.

20 The combining of Fig. 1C is part of a larger process. Computer operations take time and some commands are slower than others. For example, it takes longer to calculate the value of a portfolio containing one thousand stocks than a portfolio of one. Furthermore, it is undesirable to separate computer operations merely because they result in the generation of separate overlays because such separation may result in unnecessarily duplication of calculations.

In the preferred embodiment, unlike conventional television where information is presented strictly in the sequence of

25 events, the transmission and execution of program instruction set information for second (or subsequent) overlay can precede the transmission of the combining sync command of first overlay and the time of first overlay ceasing. To minimize waiting time, the controllers, 39, of decoders, 203, (or controllers, 44 or 47) combining sync commands that cause combining (as, for example, the commands of the second and third messages of the "Wall Street Week" example) are processed as interrupts to the CPUs of microcomputers, 205; program instruction sets, once executed, instruct microcomputer, 205, to wait only when further processing, under the control of the instructions of said sets, would entail overwriting RAM information whose overlay time or processing time has not yet ended. To prevent microcomputers, 205, that fall behind from displaying incomplete overlays, any SPAM message that causes a combining specifies the identity of the overlay whose combining it causes and causes combining only at subscriber station where information exists of completion of the overlay. For example, the second message of "Wall Street Week" causes combining only at stations where information at SPAM-first-precondition and SPAM-second-precondition memories matches selected information of the master/monitor segment of said message.

Finally, in the preferred embodiment, to restore efficient operations, microcomputer, 205, that fall behind are caused to jump over and avoid executing instructions that control the generating of overlay information [such as Fig. 1A] whose combining time has passed. In the "Wall Street Week" example, the second message causes the decoder, 145, at each subscriber station to compare SPAM-second-precondition register memory to the "00000001" of the overlay number field of said message. At stations that have not completed generating at RAM the first overlay (e.g., Fig. 1A), matches do not result, causing the controller, 39, of the decoder, 203, of said stations to execute second-condition-fail-tail instructions of the conditional-overlay-at-205 instructions. Said second-condition-fail-tail in-

structures cause each controller, 39, to compute an overlay-target number, interrupt the CPU of the microcomputer, 205, of its station, cause said CPU to execute a machine language jump to the offset address of said program instruction set that is associated with said overlay-target number, and to cause said microcomputer, 205, to continue executing the instructions of said set from the instruction at said address. In so doing, said microcomputer, 205, skips over instructions whose overlay-time has passed.

The particular overlay-target number that any given controller, 39, calculates is a function of the overlay number information of the SPAM message that invokes said conditional-overlays-at-205 instructions and also of the history-of-efficiency memory of the microcomputer, 205, of the subscriber station of said controller, 39. Particular history-of-efficiency memory exists at each controller, 39, of a decoder, 203. When said second message causes execution of said second-condition-test-failed instructions, said instructions cause said controllers, 39, to increment by one the information in said history-of-efficiency memory, thereby generating history-of-efficiency information which indicates that its associated microcomputer, 205, has failed to generate one overlay, under control of said set. Thereafter, whenever a SPAM message of 'Wall Street Week' causes one of said controllers, 39, to execute said second-condition-test-failed instructions, said instructions cause said controller, 39, to compute its overlay-target number by incrementing the overlay number information of said message by more than one and to cause the microcomputer, 205, of its station to restore its efficiency by skipping over instructions that cause the generation of more than one overlay (including one or more overlays whose overlay time has not yet come).

Thus a SPAM message that invokes said conditional-overlays-at-205 instructions causes selected stations to combine locally generated overlay information (e.g., Fig. 1A) with transmitted information (e.g., Fig. 1B) and to display combined medium information (e.g., Fig. 1C) and causes selected other stations to generate information of overlays whose combining is not caused by said message (because the overlay times of said overlays is subsequent to the time of said message). Furthermore, said message causes said other stations to generate overlays in such a way that each station generates an overlay that has a specific overlay line and the overlay times vary from station to station.

AUDIO AND OTHER OVERLAYS

Fig. 7D illustrates a radio/computer combined medium. Tuner, 209T, receives a conventional radio transmission. Decoder, 209D, splits the received transmission into two paths and transmits one to microcomputer, 205, and the other to radio decoder, 211. Decoder, 211, detects and inputs selected information to microcomputer, 205. Microcomputer, 205, has capacity to receive an audio transmission, generate and emit into audio RAM, combine audio overlay programming, and transmit the combined audio to speaker system, 209T. An example illustrates operation. A radio station transmits radio programming and embeds a SPAM message that causes microcomputer, 205, to record digital audio of statements prerecorded. "And your portfolio went up" and "But the value of your portfolio went down." The radio transmission conveys the announcer saying, "Stock prices rose today in heavy trading. Then said radio station transmits silence and embeds a SPAM command that causes microcomputer, 205, to generate and transmit audio to speaker system, 209S. System, 205, emits sound of "but your portfolio went down."

A broadcast print and computer combined medium subscriber station operates and is configured similarly to Fig. 7D. Said station has receiver apparatus analogous to radio, 209T; a programmable decoder apparatus that may consist of the decoder of Fig. 2C; a microcomputer, 205, and a printer, 221. Said decoder decodes digital information and inputs to the CPU of microcomputer, 205, and to a buffer at microcomputer, 205, that is an input buffer to said printer, 221. A SPAM message causes microcomputer, 205, to compute a value, determine said value is greater, and to said printer, 221, selected print. For example,

Stock prices rose today in heavy trading, and your portfolio went up.

Fig. 7E shows the full combined medium of television and computer. To the apparatus of Fig. 1, a divider, 202D, is added in the audio transmission path which splits the transmission into two paths and transmits one to the appropriate audio processing apparatus of TV decoder, 203, and the other to microcomputer, 205, of apparatus that has capacity for combining computer audio into the transmitted audio and that inputs its audio information to monitor, 202M. Microcomputer, 205, has audio RAM and audio synthesizing and combining capabilities.

EXAMPLE #10 CONTINUED

Microcomputer, 205, of the station of Fig. 7 and 7F holds records of the family of the subscriber. For example, information in a file named DATA_OF_URS on a disk at the A: drive specifies that said family prefers hot and spicy foods, prefers to minimize salt and consists of four adults. (Microcomputer, 205, at the station of a second subscriber holds information in DATA_OF_URS at its A: drive which specifies mild foods, indifferent regarding salt and two adults. Microcomputer, 205, of a third subscriber holds moderate foods, indifferent regarding salt, and two adults and three children.)

The program originating studio transmits a conventional television program called "Exotic Meals of India." Said

transmission is received at the intermediate station of Fig. 6 and at the aforementioned second intermediate station and retransmitted. The program is devoted to cooking fish curry. The host says, "you want a copy of the recipe tailored to your tastes for 10 cents, enter TV567#". Each subscriber enters TV567# at the local input, 225, of his station which causes said input, 225, to transmit said information to the signal processor, 200, of said station.

Later said studio transmits a message of check-ended-information instructions. Receiving said message causes controller, 20, to determine that TV567# information exists at memory, cause particular information to be placed at control-function-invoking information memory and initiate a signal record of molar information which contains TV567# information. Said studio embeds and transmits a second message of generate-recip-and-list instructions. Said message is detected at decoder, 145, and transferred to controller, 39, of decoder, 203. Said instructions cause microcomputer, 205, to generate the fish curry recipe and shopping list of the subscriber, causes said recipe and list to be printed at printer, 221, and retain information of said list at memory. Microcomputer, 205, determines that one ingredient is "Patiala's low-salt Vindaloo Curry Paste". (Stations where TV567# information was not entered discard said message.) Causing said instructions to be embedded enables any subscriber who records said programming at a recorder/player, 217, to access said instructions whenever the recorded programming is played back-and-in so doing, to cause the signal processor, 200, of his station to process molar-micromill information anew whenever TV567# is entered at a local input, 225, in the course of play back.

(An alternate method is to embed said message in a second transmission and cause a delayed All signal decoder, 290, at each of said stations to receive said second transmission, thereby causing said decoder, 290, to detect and transfer said second message to the microcomputer, 205. This method has the advantage of making the instructions relatively inulnerable to programming pirates.)

(Whichever method is employed said second message can be encrypted and decrypted in any of the methods described above.)

Said studio causes transmitting "Exotic Meals of India" for a commercial and commences transmitting program unit Q. Immediately said studio transmits said align-URS-microcomputers/205 message (#10), embodied in Q. Said message causes a controller, 20, to combine microcomputer, 205, of the computer system of said studio, Controller, 20, causes matrix switch, 258, to connect apparatus in the fashion of Fig. 7E. After an interval sufficient to allow each subscriber station so to combine, said studio transmits said sync-SRAM-reception message (#10). Said message causes decoder, 203, to detect an off-line signal and commence processing messages embodied in Q. Said studio transmits said control-invoking message (#10). Said message causes microcomputer, 205, to come under control of said studio. (The stations of said second subscriber and third subscriber come under control of said studio.) Said studio causes each intermediate station to transmit its data-module-set message. Receiving the data-module-set message of its intermediate station causes each ultimate receiver station to report information in said message in a file named "DATA_OFITS".

Said studio causes each intermediate station to transmit its specific program-instruction-set message (#10). Receiving the program-instruction-set message of its intermediate transmission station causes each ultimate receiver station to record PROGRAM_EXE information at RAM and execute the information. At the station of Figs. 7 and 7F, receiving the program-instruction-set message (#10) transmitted by the intermediate transmission station of Fig. 6 causes decoder, 203, to load and execute at microcomputer, 205, the information segment of said message (which is the program instruction set of Q, 1). (The station of said second subscriber executes said set of Q, 1. The station of said third subscriber executes the program instruction set of Q, 2.) Under control of said set of Q, 1, microcomputer, 205, generates a first video overlay and subsequent overlays. Microcomputer, 205, accesses DATA_OF_URS and locates the address of the subscriber and accesses DATA_OF_ITTS and locates the address of each market in the locality. Microcomputer, 205, computes and determines which market is closest, that the distance between said station and said market is 4.3 miles, and that said station is southwest of said market. Microcomputer, 205, stores southwest information at memory then substitutes 4.3 for X in the equation:

$$Y = 1000.00 + 62.21875 * (2.117 * X)$$

60 computes Y to be 1071.32; clears video RAM; causes the background of video RAM to be a color that is transparent when combined; causes \$1.071.32# to be placed at bit locations of video RAM. (Microcomputer, 205, of said second subscriber determines distance is 8.7, computes the Y to be 1080.64, and causes \$1.080.64# to be placed at video RAM. Microcomputer, 205, of said third subscriber substitutes 3.2 for X in its received equation:

$$Y = 1000.00 + 132.2362 * (2.0882 * X)$$

computes Y to be 1138.92 and causes "\$1,138.92" to be placed at video RAM.) Microcomputer, 205, computes the amount that the subscriber will save to be 915.93, clears audio RAM, selects audio information of "Torty-six" from D. DATA_OFITS and places said information at audio RAM.

The programming of Q conveys a picture of a person and audio of an announcer saying, "Discount Supermarkets will deliver to you, at cost, all the pork you need for this low price..."

Said studio transmits the 1st commence-outputting message (#10). Said message causes each subscriber station that has completed generation of first overlay information at video RAM to display combined information, "\$1,071.32" is displayed at monitor, 202M. (At the station of said second subscriber "\$1,080.64" is displayed. At the station of said third subscriber, "\$1,138.92" is displayed.)

Said studio transmits audio of:

"This offer represents a saving to you of over."

Said studio transmits the 2nd commence-outputting message (#10) that causes each subscriber station that has completed generation of first audio to emit its audio. The subscriber can hear:

"Simultaneously, said second subscriber can hear:

"Torty-six."

And:

"Torty-five."

is what said third subscriber can hear.)

After an interval long enough for each station to emit its audio, said studio transmits audio of:

"percent."

Receiving said 2nd commence-outputting message (#10) causes each subscriber station immediately after so transmitting one instance of its specific information at audio RAM, to continue executing instructions of its specific program instruction set at the next instruction. Automatically, each subscriber station clears audio RAM, selects information of second audio and places said information at a audio RAM.

Meanwhile, said studio transmits audio of:

"To confirm this offer, we are printing at your printer ..."

Said studio transmits a message that causes each subscriber station to commence printing. At printer, 221, hard copy emerges as:

copy emerges as:

**Discount Supermarkets offers to deliver at cost
one unit of pork to:**

**222 Second St.
Anytown, Massachusetts**

40

in exchange for this coupon and:

\$1,080.64

50 And at the station of said third subscriber:

55

**Discount Supermarkets offers to deliver at cost,
one unit of pork to:**

333 Third St.

Anothertown, Florida

In exchange for this coupon and:

\$1,138.92

- 6 subscriber causes "224-3121" to be displayed. At the station of said third subscriber "623-9000" is displayed.)
 Said studio transmits audio of.
 "On your screen to have your order delivered. Or enter on your Local Input the information that you see."
 Said studio transmits video of "TV568".
 Your Discount manager will see that all ingredients for your recipe are delivered. Enter "TV568" now and your manager promises to include one jar of Patak's®
- 5 Said studio transmits a message that causes each subscriber station that has completed generation of second audio to emit its audio. Monitor, 202M, omits:
 "Low-salt Vindaloo".
- 10 After an interval, said studio transmits audio of:
 "Curry Paste (or free.)".
 At the station of Figs. 7 and 7F, the subscriber enters TV568. Subsequently, instructions of its specific program instruction set of Q, 1 or Q, 2 cause each subscriber station where where TV568 has been inputted to telephone a shopping list order. At the station of Figs. 7 and 7F, under control of said program instruction set of Q, 1, microcomputer, 205, accesses said DATA_OFITS file; to select the telephone number of the supermarket in the vicinity of the intermediate transmission station of Fig. 6 which is 1-(800) 247-8700; and causes controller, 20, to establish telephone communications with a computer of said supermarket chain at a remote station. Then microcomputer, 205, transmits via controller, 20, to said computer the street address of the station of Figs. 7 and 7F and the shopping list of the subscriber of said station.
- 15 After time has elapsed said studio embeds and transmits the disband-JFS-microcomputer=205 message (#10). Said message causes controller, 20, to separate microcomputer, 205, from the computer system of said studio. Said message may also cause controller, 20, to cause the microcomputer, 205, to revert from broadcast control to local control and to commence processing all the instruction at which invoking broadcast control interrupted processing.
- 16 (Except for meter-reader information, the messages transmitted in example #9 to stations of field system, 93, are identical to the messages transmitted in example #10 and cause the same functionality.)
 In examples #9 and #10 apparatus at subscriber stations of particularly slow microcomputers, 205, receives difficulty. For example, receiving said 1st command-outputting message (#10) or (#9) causes at least one decoder, 203, to cause a microcomputer, 205, to jump and execute first-clear-and-continue instructions of program instruction set of Q, 1 (or of Q).

SUMMARY EXAMPLE #11

In February, 2027, farmers all over Europe decide what mix of crops to grow. Each farmer has a subscriber station identical to Fig. 7, except that each has two television recorders/players, 217 and 217A; two television tuners, 215 and 215A; and a laser disk player, 232, of each station. At each laser disc player, 232, is a file named "FARM.DAT" at the A: drive of the microcomputer, 205, of each station. At each laser disc player, 232, is a file named "PROPRIET.MOD" that contains an encrypted proprietary software module. Said module generates information of a recommended planning plan.

National planners seek to formulate policy and influence farmers' decisions. Each nation has a national intermediate transmission station identical via a satellite. At the computer, 73, of each national intermediate station, is local formula-and-item information. In a file named NATIONAL.TAX are proposed subsidy formulas and items regarding alternate crops. In a file named NATIONAL.TAX are proposed tax formulas regarding farm incomes and proposed depreciation schedules of farm equipment. And in a file named NATIONAL.MON are proposed money supply growth rates and interest rates.

Local planners seek to formulate local policies. Each local government has a local intermediate station identical to Fig. 6. In a file named LOCAL.TAX are proposed property taxes on land and equipment. In a file named LOCAL.EMP are proposed employment subsidy formulas.

At 3:00 AM GMT on February 15, 2027, the signal processor of each station commences receiving the master transmission of the European master station. At 3:10 AM, said station begins operating system instructions to all SPAM apparatus and receiver station computers, 73, and microcomputers, 205. (The master control frequency at the EPROM, 205, of each receiver station, is either said master transmission or a master channel transmission of an intermediate station on which said master transmission is retransmitted.)

Automatically, receiver stations commence tuning to transmissions that differ from station to station.

At 3:59 PM, said European master station commences transmitting program unit identification information of a combined medium television program, "Farm Plans of Europe." Farmers and planners all over Europe have programmed their stations to receive and combine to this program. Each receiver station that is not equipped with a satellite earth station turns to the master channel of its local intermediate station (which retransmits the master transmission). At 3:58-45 PM, said European master station causes each local intermediate station to tune to the second television channel of its national intermediate station, causing its computer, 73, to come under control of its national station.

At 3:58:55 PM, said European master station invokes broadcast control.

At 4:00 PM, said master station commences transmitting "Farm Plans of Europe." Immediately said station causes ultimate receiver stations to obscure all video and display locally generated information and causes all computers, 73, and microcomputers, 205, to commence receiving SPAM information embedded in the full frame video. Said master station causes microcomputers, 205, to display title.

Then said station causes ultimate receiver stations to receive a national level intermediate station that contains a national level intermediate generation set. Said master station causes the signal processor, 205, of each ultimate receiver station to input the raster frequency of its EPROM, 205, to its decoder, 20, continuously. (In so doing, said master station causes said master transmission to be inputted to said processor, 200, continuously irrespective of transmissions inputted to decoder, 145, 203, or 282, and prevents signal processor, 200, from identifying any other programming of interest.) Said master station transmits a list program instruction set. Then said master station causes all SPAM decoder apparatus to commence receiving SPAM information embedded in only the normal transmission location.

Said national level intermediate generation set causes national intermediate stations to generate a local level intermediate generation set. Said national level set includes generally applicable information of national agriculture and economic policy, of local tax formulas and items and employment subsidy formulas, and of recommended crop planting plans. Said set also contains a price at which farmers are projected to be able to sell each crop. Said set causes each national intermediate station to access its NATIONAL.AGI, NATIONAL.TAX, and NATIONAL.MON files and compute specific subsidy formulas and items, tax formulas and depreciation schedules, and monetary growth and interest rates given projected farm borrowing.

After an interval, said European master station transmits a message that causes each national intermediate station to embed in its second television channel transmission and transmit a message that contains its local level intermediate generation set.

The message of its national station causes each local intermediate station to generate a program instruction set. Each local intermediate station accesses its LOCAL.TAX and LOCAL.EMP files and computes specific local property tax and employment subsidy formulas.

At 4:29:50 PM, said master station transmits a cueing message. Said message causes each national intermediate station to embed in its second television channel a message that causes each local intermediate station to play its records, 76, and transmit the programming on its master channel. Each local intermediate station commences trans-

mitting a national and local segment of "Farm Plans of Europe".

At 4:29:55 PM, GMT, said European master network station embeds in its master transmission and transmits a message that causes each ultimate receiver station that receives said transmission by satellite to receive and process the combined medium programming of the master channel of its local intermediate station (of which information is preprogrammed in its EEPROM, 205).

In due course, each recorder, 76, transmits a message addressed to ITS computers, 73. Each local intermediate station decodes the message of its recorder, 76, and transmits its program instruction set. Subsequently, additional messages addressed to ITS microcomputers, 205, are transmitted by the recorder, 76.

Each farmer's station displays information of national and local policies combined periodically with locally generated information.

Its program instruction set causes each microcomputer, 205, to generate an optimal solution for its farmer's mix of crops problem. Each microcomputer, 205, accesses the file, MY.FARM.DAT, at its A: drive and also accesses the encrypted "PROPRIET.MOD" file that is preinstructed at laser disc player, 232. To access the "PROPRIET.MOD" file, the instructions of its particular program instruction set cause each microcomputer, 205, to decodify and enter the decrypted information of said file at particular RAM. Each microcomputer, 205, instructs its signal processor, 200, to cause its laser disk player, 232, to play. In the fashion of example #7, each station decodes and relays meter information of its "PROPRIET.MOD" file. Using linear programming techniques, each microcomputer, 205, computes its farmer's optimal crop planning plan by making reference to data that includes, for example, size of the farm, soil conditions, aspects of sunlight and shade, history of crop rotation, farm equipment, and financial resources and by applying linearization of said program instruction set. The plans include projected revenues, expenses, and profits and sensitivity analyses that are close to but not quite optimal. The microcomputer, 205, records its plan at its A: disk in a file named PLANTING.DAT.

Then automatically, under control of its program instruction set, each farmer's microcomputer, 205, computes a schedule of commercials. Information of twenty-six commercials are included in its set. Under control of its set, by analyzing the budget information of its farmer's crop planning plan, each microcomputer, 205, identifies four that are of highest potential value to its farmer. Each station inputs to said signal processor, 200, schedule information of its tour commercials. Then the recorder, 76, of each local intermediate station transmits a local cueing message addressed to ITS computers, 73.

In the fashion of example #10, each station displays and outputs generally applicable information of a crop planning plan combined periodically with specific information of its farmer. Automatically, the optimal plan of each farmer is explained.

Receiving its local cueing message causes each local intermediate station to embed a message addressed to UFS signal processors, 200, in its master channel transmission then cause its video recorder/player, 76, to output on a second television channel. Said message causes each farmer's station to receive its second television channel of its local intermediate station and transfer the transmission to a selected video recorder/player, 217 or 217A. After an interval, each computer, 73, causes said recorder, 76, to play twenty-six commercials. The signal processor, 200, of each station causes its recorder/player, 217 and 217A, to record then organize to play its selected commercial spots of its station. Automatically, said signal processor, 200, causes a selected recorder/player, 217, or 217A, to record selected programming then, after a particular last unit is received, to organize the recorded programming to play according to its schedule previously inputted by its microcomputer, 205.

The program instruction set at each farmer's station causes a module, TELEPHONE.EXE, to be recorded at the microcomputer, 205, which will permit the farmer to modify his specific plan and transmit the plan to a remote station.

A message embodied at the end of the national and local segment causes each farmer's station to separate from the master channel of its local intermediate station and is in contact to commence generating and outputting combined medium information of a selected recorder/player, 217 or 217A. Playing each commercial spot causes combined medium information to display a product such as a truck, or a software package, across "APLANTING.DAT", generate an analysis of the incremental benefit of using the product, or service, and display information of said analysis if said analysis results in a positive benefit).

Studying his plan, each farmer runs TELEPHONE.EXE and modifies his file to suit his wishes. TELEPHONE.EXE causes his signal processor, 200, to transmit his file to a computer at a remote data collection station. The data is aggregated at the computer of said European master station which allows planners to refine the variables of the national intermediate generation set, especially projected prices.

At 3:59 PM, on February 16, 2027, the cycle of generating and communicating information of farmers is repeated using refined variables. In an iterative fashion, this cycle is (repeated until a European master agricultural plan is achieved. In this fashion, the unified system of the present invention facilitates planning and decision making.

The foregoing is presented by way of example only and modifications may be made without departing from the spirit of the invention. Any message and programming transmission can, through encryption/decryption and other regulating techniques, affect only selected stations and apparatus, invoking any controlled function can also cause monitor

information to be processed. Intermediate transmission stations can be equipped with control information switching and bus communications capacity such as that illustrated in Figs. 7 and 8. Any transmission station can cause its receiver stations to function in any appropriate fashion.

Claims

1. A method of processing signals at a receiver station having a microcomputer (205) and an output device (202M) to deliver at the output device a combined output of a broadcast or cablecast program and a receiver specific datum, said method comprising the steps of:
 - (a) receiving (215) an information transmission comprising a program and one or more control signals;
 - (b) selecting said received broadcast or cablecast program from the information transmission and transferring it to the output device (202M) for delivery to the user;
 - (c) detecting (203) a specific control signal in the information transmission and passing said detected specific control signal to the microcomputer (205); and
 - (d) controlling (205) said microcomputer based on the specific control signal, said step of controlling comprising:
 - (1) generating (205) a receiver specific datum by processing information that is stored in said microcomputer;
 - (2) placing (205) said datum at a specific memory location of the microcomputer (PC-MicroKey of microcomputer 205);
 - (3) communicating (205) said receiver specific datum at said memory location to said output device (202M); and subsequently
 - (4) clearing (205) said datum from said specific memory location, whereby the combined output of said received broadcast or cablecast program and said receiver specific datum is delivered at said output device (202M) in the period of time between said step of placing said datum at said memory location and said step of clearing said datum from said memory location.
2. The method of claim 1, wherein prior to placing said receiver specific datum at the specific memory location the memory device at which said receiver specific datum is placed is cleared.
3. The method of claim 1 wherein one or more further receiver specific data are automatically communicated (205) to said output device (202M) following said receiver specific datum.
4. The method of any preceding claim wherein the step of generating a receiver specific datum by processing information that is stored in the microcomputer is achieved by executing (205) a computer program stored in the memory of the microcomputer to process said stored information, and the method further comprises the steps of:
 - (a) detecting (203) in said information transmission a first further control signal which is effective to load a computer program into the memory of the microcomputer (205).
 - (b) The method of claim 4 wherein the information transmission incorporates the computer program.
5. The method of any preceding claim wherein the step of generating a receiver specific datum by processing information that is stored in the microcomputer is achieved by executing (205) a computer program stored in the memory of the microcomputer to process said stored information, and the method further comprises the steps of:
 - (a) detecting (203) in said information transmission a first further control signal is effective to instruct the microcomputer to fetch a software module from a memory peripheral (232),
 - (b) The method of claim 4 wherein the combined output of said received broadcast or cablecast program and said receiver specific datum is delivered at the output device as part of a series of combined outputs and the steps of communicating said receiver specific datum and clearing the specific memory location are in response to one or more control signals.
6. The method of any preceding claim wherein the processing, generating, and/or outputting of said microcomputer is controlled by a programmable controller in response to control signals detected in the broadcast or cablecast information transmission.
7. The method of claim 8, further comprising the step of interrupting (35F and 39H of Fig. 3A) the controller to cause said microcomputer to communicate a receiver specific datum at a specific time.
8. The method of any preceding claim further comprising the steps of storing (205) information at the

10. The method of claim 8, further comprising the step of instructing (205, 38J) the controller to cause said microcomputer to communicate a specific receiver specific datum to said output device.
11. The method of claim 8, wherein said controller is capable of communicating an interrupt signal to a plurality of processor and/or controller devices, said method further comprising the step of programming said controller to interrupt a specific one of said plurality of processor and/or controller devices.
12. The method of any one of claims 8-11, further comprising the steps of detecting a interrupt signal in the information transmission and controlling said controller to communicate said detected interrupt signal to a processor or controller.
13. The method of any one of claims 8-12, wherein in response to the detection of said specific control signal in the information transmission the microcomputer is organized to generate said receiver specific datum as part of a series of receiver specific data, and a processor interrupt signal is inputted to the microcomputer to enable the communication of one or more specific receiver specific data to said output device at a specific time.
14. The method of claim 13, wherein said interrupt signal is inputted to said microcomputer in response to a second further control signal detected in said broadcast or cablecast information transmission, and said interrupt signal causes said microcomputer to clear the specific memory location and place a generated receiver specific datum at the specific memory location to form a subsequent combined output.
15. The method of claim 14, wherein a control signal detected in said broadcast or cablecast information transmission causes said microcomputer to cease communicating one or more receiver specific data to said output device and to commence or resume generating said series.
16. The method of any one of claims 8-12, further comprising the steps of detecting a control program in the information transmission and causing said controller to control one or more receiver station devices in accordance with said control program.
17. The method of any preceding claim wherein said receiver specific datum is not automatically communicated to said output device (202M) when said receiver specific datum is placed at said memory location, and the method further comprises the steps of:
 - (a) detecting (203) in said information transmission a third further control signal which is effective to instruct the microcomputer (205) to communicate the receiver specific datum at said memory location to said output device, whereby to cause the microcomputer (205) to communicate said receiver specific datum to the output device (202M).
 - (b) The method as claimed in claim 13, further comprising the steps of determining (38J) that said microcomputer is not prepared to communicate a first receiver specific datum to said output device at a specific time and consequently causing (39J) said microcomputer to execute a specific computer program instruction thereby to commence generating a subsequent receiver specific datum of said series.
 - (c) The method as claimed in any preceding claim, wherein the information that is stored in the microcomputer comprises user specific data and the method further comprises the steps of:
 - (i) passing (203) update data to the microcomputer (205) whereby to cause the stored user data to be updated, whereby in generating a subsequent receiver specific datum the updated user data are processed by said microcomputer.
 - (ii) The method of claim 19, wherein the update data are received in an information transmission that comprises a telephone transmission.
 - (d) The method of claim 21, wherein said update data are received in an information transmission that comprises a broadcast or cablecast information transmission for one or more update data.
 - (e) The method of claim 22, wherein said receiver station automatically initiates said telephone transmission for one or more update data.
 - (f) The method as claimed in any preceding claim further comprising the steps of storing (205) information at the

receiver station that specifies that said receiver station should automatically selectively receive a specific information transmission, and selectively receiving (200) said information transmission in accordance with said stored information.

24. The method of claim 23, wherein in response to an enabling control signal that the receiver station is enabled to receive said broadcast or cablecast program by inputting (200) to a processor one or more computer program instructions capable of controlling (200) said receiver station to receive said broadcast or cablecast information transmission, select said program, and detect said control signals.

25. The method of claim 23 or claim 24, further comprising the steps of receiving (200, Fig. 2) and storing (200, Fig. 2) advance information of transmission of said specific program.

26. The method as claimed in any preceding claim further comprising the steps of assembling records (200, Fig. 2) at the receiver station that chronic the availability, selection, and/or usage of broadcast or cablecast programs, control signals, and/or user data, and communicating (200, Fig. 2) said records to a remote data collection station.

27. The method as claimed in any preceding claim, further comprising the step of inputting (225) to a processor at the receiver station information of the reaction of a user to an output at the output device (202M).

28. The method of claim 27, further comprising the step of processing (200, Fig. 2, or 205) said user reaction information in response to a fourth further control signal detected in the broadcast or cablecast information transmission thereby to generate additional response information besides said input information.

29. The method of claim 27 or 28, further comprising the step of communicating (200, Fig. 2) at least some of said input information, or said additional response information to a remote data collection station.

30. The method as claimed in any preceding claim, wherein the broadcast or cablecast program and at least some of the control signals comprised in the information transmission are encrypted and are designated by a signal indicating an encrypted/transmission, and the method further comprises the step of controlling (200, Fig. 2) a decryptor in the receiver station to decrypt said program and encrypted control signals in response to detection of said designated signal.

31. The method as claimed in any preceding claim, further comprising the step of storing the received information transmission on a storage means (217, 225, or 256) to allow the delivery of the combined output at a time when said broadcast or cablecast program is not being received by the receiver station.

32. The method as claimed in any preceding claim, wherein the output device is one or more from the group consisting of a printer (221) for outputting printed information, a sound generator (253) for outputting sounds, a video display device (202M) for displaying video information, a video storage device (217) for storing video information, an audio storage device (255) for storing audio information, and an intermediate transmitter (92).

33. The method of claim 32 wherein the output device is a TV monitor (202M), said specific memory location is a video RAM, and said receiver specific datum is cleared from said memory location by placing information of a change color at said memory location and said change color appears transparent when displayed at said monitor in combination with a television image.

34. The method of claim 33 wherein the specific memory location of the microcomputer at which the receiver specific datum is placed is selected on the basis of determining a reference point and scalar dimension for the receiver specific datum in the step of generating (205) said receiver specific datum.

35. The method as claimed in any preceding claim, wherein said receiver station is one of a plurality of similar receiver stations receiving the same information transmission, the generated receiver specific datum at each station being specific to its receiver station, and the series of receiver specific data generated at the receiver stations differing from station to station.

36. The method of claim 35, wherein a time period separating the receiver stations' receipt of the specific control signal and the receiver stations' receipt of the third further control signal is sufficient to allow each receiver station microcomputer to complete said step of generating before each receiver station microcomputer receives said first further

control signal.

37. A receiver station apparatus for processing signals to deliver a combined output of a broadcast or cablecast program and a receiver specific computer generated datum, said station having an output device (202M) for delivering the broadcast or cablecast program and other information, said apparatus comprising:

a decoder (203) comprising means for:

- (1) receiving an information transmission comprising a broadcast or cablecast program and one or more control signals;
- (2) detecting the presence of the control signals in the information transmission; and
- (3) parsing the detected control signals to a microcomputer (205);

said microcomputer (205) being operatively connected to said output device (202M) and said decoder (203), said microcomputer (205) having a specific memory location (PC-MicroKey) of microcomputer (205) connected to said output device (202M) for communicating data stored in said specific memory location (PC-MicroKey) of microcomputer (205) to said output device (202M), and said microcomputer (205) being programmed to perform the following steps based upon one or more specific control signals:

- (1) generating a receiver specific datum by processing information that is stored in said microcomputer (205) in response to receiving a specific signal;
- (2) placing said receiver specific datum in said specific memory location (PC-MicroKey) of microcomputer (205);
- (3) communicating said receiver specific datum at said memory location to said memory location subsequently;
- (4) clearing said datum from said specific memory location (PC-MicroKey of microcomputer 205), thereby delivering a combined output of said received broadcast or cablecast program and said receiver specific datum at said output device (202M) in the period of time between said step of placing said datum at said memory location (PC-MicroKey of microcomputer 205) and said step of clearing said datum from said memory location (PC-MicroKey of microcomputer 205).

38. The apparatus of claim 37, wherein said output device is a video output device (202M) and said detected control signal is a signal which controls said microcomputer (205) to place a receiver specific video datum at said specific memory location, said apparatus further comprising a video output memory (PC-MicroKey of 205) connected to said microcomputer (205) and said video output device (202M) for communicating video information to said video output device (202M).

39. The apparatus of claim 37 or claim 38, wherein said output device is an audio output device (203) and said detected control signal is a signal which controls said microcomputer (205) to place a receiver specific audio datum at said specific memory location, said apparatus further comprising an audio output memory (audio RAM of 205) connected to said microcomputer (205) and said audio output device (202M) for communicating audio information to said audio output device (202M).

40. The apparatus of any one of claims 37-39, further comprising a programmable controller (39 of decoder 203) connected to said microcomputer (205) for controlling the processing, generating and/or outputting of said microcomputer (205) in response to control signals detected in a broadcast or cablecast information transmission.

41. The apparatus of claim 40 wherein said controller (39 in Fig. 2A, 44 in Fig. 2B, 47 in Fig. 2C) is operatively connected to said decoder (203), said apparatus further comprising a programmable control processor (39J in Fig. 3A) for controlling the communication of information detected in said information transmission.

42. The apparatus of claim 41 wherein said controller (39) inputs a computer program to a selected processor (39J, CPU of 205) or controller (39, 20 of 200) or causes a selected processor (39J, CPU of 205) or controller (39, 20 of 200) to modify a manner of identifying or responding to a control signal in said information transmission, said apparatus further comprising a selective transmission device (13 in Fig. 2D, 39I in Fig. 3A, 259 in Fig. 7) for communicating information detected in said information transmission to said selected processor (39J, CPU of 205) or controller (39, 20 of 200).

43. The apparatus of claim 42, wherein said selective transmission device (13 in Fig. 2D, 39I in Fig. 3A, 259 in Fig. 7)

EP 0 382 764 B1

EP 0 382 764 B1

44. The apparatus of any one of claims 41-43, wherein any one of said controller (39), said control processor (39), said microcomputer (39) or a plurality of processors (39B, 39D, 39J) or a single microchip (39, Fig. 3A).
45. The apparatus of any one of claims 37-44, wherein the microcomputer (205) receives an input comprising a computer program and one or more interrupt signals and generates said receiver specific datum in accordance with said computer program or clears said specific memory location in response to said one or more interrupt signals, said apparatus further comprising one or more buffers (B, 39A, 39C, 39E, 39G, in 205) or memories (in 39B, in 39D, in 39J, 217, 217A) for storing and communicating said computer program to said microcomputer (205).
46. The apparatus of any one of claims 37-45, wherein a processor (39J, 1, 200) communicates a control instruction based on a record of the presence or absence of a program or a receiver specific datum, said apparatus further comprising a memory (SPAM) first precondition and SPAM-second precondition register memories in 39J; in 20, 14 or 16 in 200) for storing one or more records of the presence or absence of a program or a receiver specific datum.
47. The apparatus of claim 45 when appended to claim 40 or of claim 46, wherein the controller (39) of decoder (203) inputs an interrupt signal to said microcomputer (205) to cause said microcomputer (205) to communicate a receiver specific datum at a specific line.
48. The apparatus of any one of claims 37-47, wherein a receiver specific datum is outputted in response to a reaction of user to an output at said output device (202M), said apparatus further comprising an input device (225) for inputting information of a reaction of a user to an output, and a processor (200, CBU or 205) operatively connected to said input device (225) for processing the inputted information of a reaction of a user.
49. The apparatus of any one of claims 37-48, wherein said station outputs to a remote station a record that chronicles the availability, use and/or usage of a program, a control signal, or a combined output at said receiver station or some input of the reaction of a user to a combined output of a received broadcast or cablecast program and a receiver specific datum at said output device (202M), said apparatus further comprising a transmitting device (telephone connection 22) for communicating input to a remote station.
50. The apparatus of any one of claims 37-49, wherein said specific control signal causes said microcomputer (205) to access and retrieve data stored at a computer peripheral (A, disk drive or computer (205)), said apparatus further comprising a computer peripheral memory unit (232, 256) connected to said microcomputer (205) for storing said data to be retrieved.
51. The apparatus of any one of claims 37-50, further comprising a memory (in 20 or 200) connected to a receiver (mixer 3 of Fig. 2) for storing information of a selected program and receiving from a remote station information of a time or frequency of the transmission of said program and a controller (20) connected to said memory (in 20) and to a tuner (214) for causing said station to receive said selected program at said time or in said frequency.
52. The apparatus of any one of claims 37-51, further comprising a storage device (217, 255, 256) connected to a receiver (20, 215) or an output device (202M) for receiving and storing, whereby at least some information of a received program and a received control signal or a receiver specific datum is stored for later shifted output to a user.
53. The apparatus of any one of claims 37-52, further comprising a descrytptor or descrambler (224) connected to a receiver (20) to enable descrypting or descrambling of information of a received program or a received control signal which is encrypted or scrambled.
54. The apparatus of any one of claims 37-53, further comprising a selective transmission device (258) (or communicating the program from a receiver (20, 215) or storage device (217, 217A) to a storage device (217, 217A)) or an output device (202M).
55. The apparatus of any one of claims 37-54, wherein said information transmission is a multichannel transmission, said apparatus further comprising a converter (201) for receiving and converting some portion of said multichannel transmission and converting some portion of said multichannel transmission to a specific output frequency.
56. The apparatus of any one of claims 37-55, further comprising a printer (221) and a print output memory location (print buffer of 205) connected to said microcomputer (205) and said printer (221) for communicating print information to said printer (221).
57. The apparatus of any one of claims 37-56, wherein said program is a television program, said apparatus further comprising a television tuner (215) for receiving a television signal containing said program and a television monitor for outputting said television program and said receiver specific datum.
58. The apparatus of claim 37 and any one of claims 39-56, wherein said program is a radio program, said apparatus further comprising a radio tuner (209) for receiving a radio program and a speaker system (263) for outputting said program and said receiver specific datum.
59. A method of communicating mass medium program material to a plurality of receiver stations each of which includes a broadcast or cablecast program receiver (215), an output device (202M), a control signal detector (decoder 203), a microcomputer (205) with a specific memory location (PC-MicroKey or microcomputer 205) capable of communicating to said output device (202M), and with each said receiver station adapted to detect the presence of one or more control signals, to generate a receiver specific datum in response to a detected specific control signal, and to deliver at said output device a combined output of the broadcast or cablecast program and the receiver specific datum, said method of communicating comprising the steps of:
- 1) receiving a program to be transmitted and delivering the program to a transmitter;
 - 2) receiving and storing a control signal which at the receiver station operates to generate the receiver specific datum; and
 - 3) causing the stored control signal to be communicated to the transmitter at a specific line.
60. The method of claim 59, wherein said information transmission is transmitted to two of said plurality of receiver stations at the same time and each of said two receiver stations delivers its combined output of said received broadcast or cablecast program and its generated receiver specific datum at its output device (202M) in the same period of time.
61. The method of claim 59, wherein said information transmission is transmitted to two of said plurality of receiver stations at different times and each of said two receiver stations delivers its combined output of said received broadcast or cablecast program and its generated receiver specific datum at its output device (202M) in a different period of time.
62. The method of any one of claims 59-61, wherein a memory location is operatively connected to a computer for receiving and storing some information of said control signal, said method further comprising the steps of detecting a signal which is effective at the transmitter station to generate, and inputting said transmitter generated signal to said computer thereby to cause said computer to generate some information of said control signal and place said generated information at said memory location.
63. The method of claim 62, further comprising the step of programming said computer to respond to said transmitter generated signal by processing information stored in said computer.
64. The method of claim 62 or claim 63, wherein said computer processes specific formula-and-item-of-this-transmission information in response to said transmitter generated signal, further comprising the steps of inputting formula-and-item data to said computer.
65. The method of any one of claims 62-64, further comprising generating some portion of one of a computer program and a data module in response to said transmitter generated signal.
66. The method of any one of claims 59-65, further comprising the steps of causing a memory location that is capable of storing and communicating a computer program, to communicate a computer program to a transmitter or to transmit said computer program, thereby to cause at least one receiver station to load said computer program at a processor and cause said processor to generate and output information under the control of said computer program.
67. The method of claim 66, further comprising the step of assembling said stored and communicated computer program into a message with a plurality of segments, and said computer program is located in a specific portion of

- said message and said message includes information that causes at least one receiver station to input said computer program to a selected one of a plurality of processors.
68. The method of claim 66 or claim 67, further comprising the steps of causing a memory location that is capable of storing and communicating an instruct signal to communicate said instruction signal to a computer in order to generate a portion of said computer program at said computer in response thereto.
69. The method of any one of claims 59-65, wherein said transmitter station transmits one or more of a video, an audio and a data signal received from a remote station, said method further comprising the step of storing said received one or more of a video, an audio and a data signal for a period of time, whereby transmission of said received one or more of a video, an audio, an audio, and a data signal is delayed.
70. The method of any one of claims 59-69, wherein a controller controls the passing of a specific received signal, said method further comprising the steps of detecting embedded information in said specific received signal and controlling the passing of said specific received signal on the basis of said detected embedded information.
71. The method of claim 70, wherein said controller controls a switch, said method further comprising controlling said switch to communicate signals selectively from one or more program input receivers and one or more memory locations to one or more memory locations and one or more transmitters.
72. The method of claim 71, wherein said transmitter station transmits a plurality of messages to one of said plurality of receiver stations to control said one receiver station to deliver its combined output of said program and its receiver specific datum at its output device, said method further comprising the steps of communicating a signal containing one of said plurality of messages from a program input receiver to a memory location and subsequently communicating said signal containing said one of said plurality of messages from said memory location to a transmitter.
73. The method of any one of claims 70-72, wherein said transmitter station stores at least one program, said method further comprising the steps of receiving said program at a program input receiver, communicating said program to a storage device, and storing said program at said storage device with an instruct signal which is effective at the transmitter station to control one of said computer and said controller.
74. The method of claim 73, further comprising the steps of detecting said instruct signal and communicating said instruct signal to one of said computer and said controller.
75. The method of claim 71 and any one of claims 72-74, when appertaining to claim 71, further comprising the step of controlling said switch on the basis of the presence or absence of an instruct signal stored with a program.
76. The method of any one of claims 59-75, wherein said transmitter station includes a plurality of program input receivers, said method further comprising the steps of processing signals received at said plurality of program input receivers, communicating control information in response to an arbitration decision, and controlling the passing of a signal received at a specific one of said plurality of program input receivers on the basis of said communicated control information.
77. The method of any one of claims 59-76, wherein said program and said receiver generate signal are received from one or more remote stations, said method further comprising the steps of processing a signal received from said one or more remote stations and controlling said transmitter station to communicate said program to a transmitter, or said receiver generate signal to said computer, on the basis of information in said processed, received signal.
78. The method of any one of claims 59-77, further comprising the steps of receiving said program at a receiver in the transmitter station, communicating said program from said receiver to a memory location, and storing said program at said memory location for a period of time prior to communicating said program to a transmitter.
79. The method of claim 78, further comprising the steps of receiving said program at a selected one of a plurality of receivers in the transmitter station and communicating said program from said selected receiver to a transmitter.
80. The method of any one of claims 78-79, further comprising the steps of transmitting said program at a selected one of a plurality of transmitters and communicating said program to said selected transmitter.

81. The method of any one of claims 55-80, wherein a switch communicates received signals selectively from at least one receiver and at least one memory location to a transmitter, said method further comprising the steps of inputting a signal which is effective at the transmitter station to instruct communication, and controlling said switch to communicate a received signal from a receiver to a memory location in response to said instruct signal.
82. The method of claim 81, when appertaining to claim 62, wherein said received signal contains said transmitter generated signal, said method further comprising the step of subsequently communicating at least some of said transmitted generated signal from said memory location to a second memory location.
83. The method of claim 81, wherein said received signal contains said program, said method further comprising the step of controlling said switch to communicate said program to a transmitter.
84. The method of any one of claims 59-83, wherein a plurality of signals is received from one or more remote stations at said transmitter station, said method further comprising the steps of selecting one or more of said plurality of signals, and communicating each selected signal to a storage device.
85. The method of claim 84, when appertaining to claim 70, wherein one or more of said selected signals is a signal which is effective at the transmitter station to instruct one of said computer and said controller, said method further comprising the step of causing a memory location to communicate said instruct signal prior to said specific line and controlling said one of said computer and said controller in response to said instruct signal.
86. The method of any one of claims 59-85, wherein a plurality of signals is received from one or more remote stations and at least one is stored at said transmitter station and one of said plurality of received signals is operative to schedule, said method further comprising the steps of programming said transmitter station to store the schedule and causing said transmitter to transmit in accordance with the schedule.
87. The method of claim 86, further comprising the step of causing said transmitter station to generate in accordance with the schedule.
88. The method of claim 86 or claim 87, further comprising the step of tuning a receiver or controlling a satellite earth station to receive a signal in accordance with the schedule.
89. The method of any one of claims 59-88, further comprising the steps of receiving an information transmission from a remote station, detecting in the information transmission an instruct signal which is effective at the transmitter station to execute an instruction set, loading an instruction set at a computer in response to said instruct signal, and on the basis of said instruction set, selecting information to be processed at a receiver station or communicating information to be associated with said program.
90. The method of any one of claims 59-89, wherein a controller controls a memory location to communicate to a transmitter a selected control signal, said method further comprising the steps of detecting a signal which is effective at the transmitter station to instruct transmission, and inputting said signal to said controller thereby to cause said memory location to communicate a selected control signal.
91. The method of claim 90, further comprising the step of programming said controller to respond to a said signal by controlling a selected memory location to communicate a control signal or by ceasing a memory location to communicate a selected control signal.
92. The method of claim 90 or claim 91, wherein the instruct transmission signal is received in a broadcast or cablecast information transmission transmitted by a remote station.
93. The method of any one of claims 90-92, further comprising the steps of storing a signal which is effective at the transmitter station to instruct, and controlling said memory location to communicate a selected control signal at a scheduled time according to said instruct signal.
94. The method of any one of claims 90-93, further comprising the step of storing said signal at said memory location with said program.
95. The method of any one of claims 90-94, further comprising the steps of controlling a memory location to commun-

- nicate said program to a transmitter in response to a first instruct signal and controlling a memory location to communicate a selected control signal in response to a second instruct signal.
96. The method of claim 95, further comprising the steps of detecting a control signal communicated from said memory location and programming a controller to respond to a control signal communicated from said memory location.
97. The method of any one of claims 90-96, further comprising the steps of embedding an instruct signal in said program thereby to enable a controller to respond to said embedded instruct signal at a time when said program is being communicated.
98. The method of claim 84 and of any one of claims 65-97 when appended to claim 64, wherein said transmitter generates signal or said formula-and-item data is received in a broadcast or cablecast information transmission transmitted by a remote station, said method further comprising the steps of receiving an instruct signal from a remote station and transmitting said formula-and-item information in response thereto.
99. The method of any one of claims 59-98, further comprising the steps of storing a signal which is effective at the transmission station to instruct generation, and controlling a computer to process stored information before said specific line according to said stored instruct signal.
100. The method of any one of claims 59-99, further comprising the steps of storing and transmitting to a receiver station data that specifies a time of transmission of or a channel of transmission of or some subject matter of a specific program, and subsequently transmitting said program in accordance with said specified data thereby to enable said receiver station to select and store or select and output said program.
101. The method of any one of claims 59-100, further comprising the steps of transmitting to a receiver station a control signal to cause said receiver station to align to a parallel processing system and select and input to a microcomputer some information associated with a program or control signal transmitted in broadcast or cablecast information transmission and cause said microcomputer to process stored information and generate output in response to said inputted information.
102. The method of claim 100 or 101, further comprising the steps of communicating to a signal generator data that specifies a time of transmission of or a channel of transmission of or some subject matter of a specific program or a control signal and adding said communicated data or control signal to a specific part of a broadcast or cablecast information transmission or adding said communicated data or control signal to a broadcast or cablecast information transmission in a message of a specific format.
103. The method of any one of claims 59-102, further comprising the steps of causing a memory location that is capable of storing and communicating a signal which is effective at the receiver station to synchronize, to communicate said signal to a transmitter to transmit said signal, thereby to cause at least one receiver station to interrupt the processing of selected controlled functions programmed at said one station in response to selected information in the broadcast or cablecast information transmitted by said transmitter.
104. The method of any one of claims 59-103, further comprising the steps of causing a memory location that is capable of storing and communicating a signal which is effective at the receiver station to interrupt, to communicate said signal to a transmitter to transmit said signal, thereby to cause at least one receiver station to interrupt the processing of a selected microcomputer, controller, or processor in response thereto.
105. The method of any one of claims 59-104, further comprising the steps of causing a memory location that is capable of storing and communicating a signal which is effective at the receiver station to serve as a source from which to select a receiver specific datum to be generated, to communicate the signal to a transmitter to transmit said signal, thereby to cause at least one receiver station to select a receiver specific datum to be generated.
106. The method of claim 105, wherein said signal which is effective at the receiver station to serve as a source is transmitted before said receiver generates signal, whereby at least one receiver station stores data received in said source signal and generates a receiver specific datum by processing said stored data.
107. The method of any one of claims 59-106, further comprising the steps of causing a memory location that is capable of storing and communicating a signal which is effective at the receiver station to cease combining, to communicate

- the signal to a transmitter to transmit said signal, thereby to cause at least one receiver station to cease combining its generated receiver specific datum at a specific time.
108. The method of any one of claims 59-107, further comprising the steps of causing a memory location that is capable of storing and communicating a signal which at least one receiver station operates to combine to communicate the signal to a transmitter to transmit said signal, thereby to cause at least one receiver station to deliver a combined output of said received broadcast or cablecast program and said receiver specific datum at its output device at a specific time.
109. The method of any one of claims 59-108, further comprising the steps of causing a memory location that is capable of storing and communicating a signal which at the receiver station operates to clear a generated receiver specific datum, to communicate said signal to a transmitter to transmit said signal, thereby to cause at least one receiver station to clear its generated receiver specific datum in response thereto.
110. The method of any one of claims 59-109, further comprising the steps of detecting a signal which is effective at the transmitter station to instruct generation, in one of a television signal and a radio signal or at a memory location that stores one of a television program or a radio program.
111. The method of any one of claims 59-110, wherein the receiver station is a remote intermediate transmitter station, the output device (202N) is a transmitter (83, 87, 91, 92), the microcomputer (205) is an automatic control unit (73) for the intermediate transmitter station, and the specific memory location is a program-set-to-transmit memory, said method further comprising the steps of:
- (1) receiving one or more instruct signals which are effective at a subscriber station to instruct a computer (73, 205) or processor (in 71, 200, 35);
 - (2) receiving one or more control signals which at the remote intermediate transmitter station operate to execute or communicate said one or more instruct signals; and
 - (3) causing said one or more control signals to be communicated to said transmitter before said specific time,
- thereby to transmit an information transmission comprising the one or more instruct signals and one or more control signals.
112. The method of any one of claims 59-111, wherein the receiver station is a remote intermediate transmitter station, the output device (202K) is a transmitter (83, 87, 91, 92), the microcomputer (205) is an automatic control unit (73) for the intermediate transmitter station, and the specific memory location is a memory (73) or recorder (76 or 78), said method further comprising one of the steps of:
- (1) receiving said program and delivering said program to a transmitter before said specific time;
 - (2) receiving one or more instruct signals which are effective at a subscriber station to instruct a computer (73, 205) or processor (in 71, 200, 35);
 - (3) receiving one or more control signals which at the remote intermediate transmitter station operate to select or communicate said program or said one or more instruct signals and delivering said one or more control signals to a transmitter before said specific time; and
 - (4) receiving a schedule which at the remote intermediate transmitter station operates to transmit said program and said one or more instruct signals and delivering the schedule to a transmitter before said specific time,
113. The method of any one of claims 59-112, wherein a transmitter station receives from a subscriber station some information of a reaction of a subscriber to a television programming or computer output presentation, said method further comprising at least one of the steps of:
- (1) transmitting to a subscriber station a computer program that processes some information of a reaction of a subscriber to a television programming or computer output presentation;
 - (2) refining some variable of an instruct signal on the basis of a reaction of a subscriber to a television programming or computer output presentation; and

transmitting some portion of a television programming or computer output presentation.

114. The method of any one of claims 59-113, further comprising the steps of causing one transmitter station to transmit said program and causing a second transmitter station to transmit said control signal which at the receiver station operates to generate the receiver specific datum or to transmit a data module which at the receiver station serves as a source of a receiver specific datum to select and generate.

115. The method of any one of claims 59-114, wherein said program is transmitted to a subscriber station by satellite and a second transmitter station is caused to broadcast or cablecast to said subscriber station said control signal or a data module associated with said program.

116. The method of any one of claims 59-115, further comprising transmitting a plurality of programs and one or more signals which are effective at a subscriber station to analyze a value or generate a schedule, thereby to cause at least one subscriber station to select one of said plurality of programs on the basis of its potential value to a subscriber or to output two or more of said programs in a receiver specific order.

117. A transmitter station apparatus for processing signals and communicating mass medium program materials to present at each of a plurality of receiver stations a combined output of a broadcast or cablecast program and a receiver specific computer generated datum, with each of said receiver stations having an output device (202M) for receiving and delivering the broadcast or cablecast program and other information, said station also having a microcomputer (205) with a specific memory location (PC-MicroKey or microcomputer 205) operatively connected to said output device (202M) for storing and outputting information to said output device (202M), said transmitter station apparatus comprising:

a broadcast or cablecast transmitter (83, 87, 91 or 92) for communicating to a plurality of receiver stations an information transmission comprising a program and one or more control signals, a program input receiver (76, 78, 53-52) operatively connected to said transmitter (83, 87, 91 or 92) for communicating the program to said transmitter (83, 87, 91 or 92); and a memory (73) or recorder (76 or 78) operatively connected to said transmitter (83, 87, 91 or 92) for storing and communicating a control signal which at the receiver station operates to generate the receiver specific datum; and an input device (98, 74, 50-62) operatively connected to said memory (73) or recorder (76 or 78) for causing said memory (73) or recorder (76 or 78) to communicate said control signal at a specific time to said transmitter (83, 87, 91 or 92), thereby to communicate said program and said control signal to said receiver station and cause each of said plurality of receiver stations to deliver said program at its output device (202M), generate (205) a receiver station specific datum, place its receiver station specific datum at its memory location (PC-MicroKey or microcomputer 205) for a period of time, and deliver a combined output of said broadcast or cablecast program and its receiver station specific datum at its output device (202M).

118. The transmitter station apparatus of claim 117, wherein said transmitter station transmits to said plurality of receiver stations a first transmitter specific datum and at least one of said plurality of receiver stations outputs said second transmitter specific datum at its output device (202M), said apparatus further comprising:

a third memory (73) or recorder (76 or 78) operatively connected to said transmitter (83, 87, 91 or 92) for storing and communicating some data which at the receiver station serve as a source from which to select a receiver specific datum to be generated.

119. The transmitter station apparatus of any one of claims 117-118, wherein said transmitter station transmits to said plurality of receiver stations a second transmitter specific datum and at least one of said plurality of receiver stations outputs said second transmitter specific datum at its output device (202M), said apparatus further comprising:

a third memory (73) or recorder (76 or 78) operatively connected to said transmitter (83, 87, 91 or 92) for storing and communicating some data which at the receiver station serve as a source from which to select a receiver specific datum to be generated.

120. The transmitter station apparatus of any one of claims 117-119, wherein said input device inputs a first advance signal which is subsequently effective at the transmitter station at said specific time to output said first named memory (73) or recorder (76 or 78) to said transmitter (83, 87, 91, or 92), said apparatus further comprising:

a first processor (73) operatively connected to said input device (50-62, 74, 98) for distinguishing an advance signal; a first memory controller (73, 205C in 73) operatively connected to said first processor (73) for controlling a fourth memory (73) or recorder (76 or 78) to store one or more advance signals; and a fourth memory (73) or recorder (76 or 78) operatively connected to said first controller (73, 205C in 73) for storing said first advance signal.

121. The transmitter station apparatus of any one of claims 117-120, wherein said input device (98, 74, 50-62) inputs an instruct signal which is effective at the transmitter station to output said first named memory (73) or recorder (76 or 78) to said transmitter (83, 87, 91 or 92) at said specific time, said apparatus further comprising:

a first control processor (39, 73) operatively connected to said input device (98, 74, 50-62) for distinguishing a signal which is effective at a said transmitter station to instruct; and a first output controller (73, 205C in 73, 35 in any decoder, 12 in 71) operatively connected to said first control processor (73) for outputting a control signal which is effective to output a memory (73) or recorder (76 or 78).

122. The transmitter station apparatus of any one of claims 117-121, further comprising at least one of:

a first selective transmission device controller (73) operatively connected to said program input receiver (76, 78, 53-62) for controlling a first selective transmission device (75, 76, 78, 53-62) to communicate one or more signals to a memory (73) or recorder (76 and 78) before a specific time;

a second selective transmission device controller (73) operatively connected to said broadcast or cablecast transmitter (83, 87, 91, 92) for controlling a second selective transmission device (73, 75, 76, 78) to communicate one or more signals from one or more memories (73) and/or recorders (76 or 78) at a specific time.

123. The transmitter station apparatus of any one of claims 117-122, further comprising:

a central controller (73) operatively connected to one of said program input receiver (76, 78, 53-62) and said broadcast or cablecast transmitter (83, 87, 91, 92) for controlling the communication to said one of some portion of said program, some of a message to be associated with said program, one or more data that identify said program, some advance information of said program, one or more data that designate the starting point of some portion of said program, or a signal that designates said program and is effective at the receiver station to instruct.

124. The transmitter station apparatus of claim 123, further comprising one of:

a clock operatively connected to said central controller (73); and a second input device (98, 74, 50-62) operatively connected to said central controller (73) for inputting one or more timing control instructions.

125. The transmitter station apparatus of claim 123 or claim 124, further comprising one of:

a second processor (73, in 71, in any decoder) operatively connected to said central controller (73) for distinguishing a timing control signal or a time at which to pass a signal which is effective to instruct;

a second memory controller (73) operatively connected to said central controller (73) for controlling a selected memory (73) or recorder (76 or 78) to store an advance signal which is effective to instruct; and a fifth memory (73) or recorder (76 or 78) operatively connected to said central controller (73) for storing two or more signals in order.

126. The transmitter station apparatus of any one of claim 119 and claims 120-125 when appended on claim 119, further comprising:

a first computer (73) operatively connected one of said second memory (73) or recorder (76 or 78) and said third memory (73) or recorder (76 or 78) for receiving formula-and-item data, and for outputting same portion of a data module to that one memory (73) or recorder (76 or 78);

127. The transmitter station apparatus of any one of claims 117-126, wherein, some of said control signal is formula-and-item-of-itself transmission information, said apparatus further comprising:

A second computer (73) operatively connected to said first named memory (73) or recorder (76 or 78) for outputting formula-and-item-of-itself transmission information in response to an instruction which is effective at

the transmitter station to generate.

128. The transmitter station apparatus of any one of claim 120 and claims 121-127 wherein appellant to claim 120, wherein a signal containing said program inputs a coded advance signal which is effective at the transmitter station to output said first memory (73) or recorder (76 or 78) to said transmitter (53, 87, 91, or 92), said apparatus further comprising:
- 6 a first decoder (in 71, 77, 79) operatively connected to said input device (98, 74, 50-62) for decoding information coded in a signal containing a program.
- 10 a third selective transmission device (in 39, in 71) operatively connected to said first decoder (in 71) for communicating to said first processor (in 39, in 71) one or more data.
129. The transmitter station apparatus of claim 128 when appended to claim 122, wherein said transmitter station includes said first selective transmission device controller (73) and said decoder (in 71, 77, 79) decodes one or more data which are effective at the transmitter station to delay communication to the receiver station of some portion of said signal containing said program, said apparatus further comprising:
- 15 a fourth selective transmission device (in 39, in 71) operatively connected to said first decoder (in 71) for communicating to said first control processor (in 39, in 71) one or more data; and
- 20 a fifth selective transmission device (in 39, in 71) operatively connected to said first control processor (in 39, in 71) for communicating to said first selective transmission device controller (73) a signal which is effective to instruct.
130. The transmitter station apparatus of any one of claims 117-129 wherein said input device (98, 74, 50-62) includes a first receiver (50-62, 71, 73) for receiving from a remote station a signal which is effective at the transmitter station to instruct.
- 25 131. The transmitter station apparatus of any one of claims 117-130, wherein said first computer (73) or said second computer (73) generates some output in response to an instruct signal which is effective at the transmitter station to generate, said apparatus further comprising:
- 30 a sixth memory (73) or recorder (76 or 78) for storing an instruct signal that is effective at the transmitter station to generate; and
- 35 a third input device (73, 74, 98, in 71) operatively connected to said sixth memory (73) or recorder (76 or 78) for causing said sixth memory (73) or recorder (76 or 78) to output at a second specific time an instruct signal that is effective at the transmitter station to generate; and
- 40 a sixth selective transmission device (73) operatively connected to said sixth memory (73) or recorder (76 or 78) for receiving and transmitting one or more instruct signals.
- 45 132. The transmitter station apparatus of claim 131 further comprising:
- 46 a third processor (73) operatively connected to said second input device (73, 98, in 71) and said second memory controller (73) for distinguishing an instruct signal which is effective at the transmitter station to generate and causing said second memory controller (73) to control said sixth memory (73) or recorder (76 or 78) to store said distinguished instruct signal.
- 50 133. The transmitter station apparatus of claim 131 or 132 wherein said second input device (73, 74, 98, in 71) receives from a second remote station said instruct signal which is effective at the transmitter station to generate.
- 55 134. The transmitter station apparatus of any one of claims 131-133, further comprising:
- 56 a SPAW-controller (205C) in 73, 39 in any decoder, 12 in 71) operatively connected to a specific computer (73) for controlling said specific computer (73) to generate or output a computer program or a data module in accordance with an instruct signal that is effective at the transmitter station to generate.
- 60 135. The transmitter station apparatus of any one of claims 128-134, wherein said program input receiver (76, 78, 53-62) inputs a coded instruct signal which is received with said program and is effective at the transmitter station to generate, said apparatus further comprising:
- 65 a seventh selective transmission device (in 71, in 77, in 79) operatively connected to said first decoder (in 71,

- 77, 79) for receiving and transferring a decoded signal; and
- 6 a fourth processor (73, in 71, in 77, in 79) operatively connected to said seventh selective transmission device (in 71, in 77, in 79) for distinguishing a device to which to pass a signal which is effective at the transmitter station to instruct.
136. The transmitter station apparatus of any one of claims 117-135, wherein said transmitter station transmits one or more signals that are effective at the receiver station to instruct the specific memory location to combine or cease combining or clear a receiver specific computer generated datum, said apparatus further comprising:
- 10 a fourth input device (50-62, 74, 98) operatively connected to a broadcast or cablecast transmitter (63, 87, 91, or 92) for communicating to said broadcast or cablecast transmitter (63, 87, 91, or 92) at a third specific time one or more signals which are effective at the receiver station to instruct.
137. The transmitter station apparatus of claim 136, wherein a third remote station communicates said one or more signals which are effective at the receiver station to instruct, said apparatus further comprising:
- 15 a second receiver (50-62, 71, 73) operatively connected to a selective transmission device (73, 75, in 71, 39 in any decoder) for receiving from a remote station one or more signals which are effective at the receiver station to instruct.
138. The transmitter station apparatus of claim 136 or claim 137, further comprising:
- 20 a seventh memory (73) or recorder (76 or 78) operatively connected to a selective transmission device (73, 75, in 71, 39 in any decoder) for storing one or more signals which are effective at the receiver station to instruct; and
- 25 a fifth input device (50-62, 74, 98) operatively connected to said seventh memory (73) or recorder (76 or 78) to output to a broadcast or cablecast transmitter (63, 87, 91, or 92) at a specific time one or more signals which are effective at the receiver station to instruct.
139. The transmitter station apparatus of any one of claims 117-138, wherein said program input receiver (76, 78, 53-62) is a memory (73) or recorder (76 or 78) at which at least some of said program is stored, said apparatus further comprising:
- 30 a sixth input device (50-62, 74, 98) operatively connected to said program input receiver (76, 78, 53-62) for causing said program input receiver (76, 78, 53-62) to commence outputting said program to a broadcast or cablecast transmitter (63, 87, 91, or 92) at a fourth specific time.
- 35 140. The transmitter station apparatus of claim 139, further comprising:
- 36 an eighth memory (73) or recorder (76 or 78) for storing one or more data that designate the starting point of a portion of a program, and
- 40 a second output controller (73, 205C) in 73, 39 in any decoder, 12 in 71) operatively connected said eighth memory (73) and to said program input receiver (76, 78, 53-62) for controlling said program input receiver (76, 78, 53-62) to commence outputting a portion of a program at the beginning of said portion.
- 45 141. The transmitter station apparatus of claim 139, wherein said sixth input device (50-62, 74, 98) inputs an instruct signal which is effective at the transmitter station to output said program at said fourth specific time, said apparatus further comprising one of:
- 46 a fifth processor (73) operatively connected to said fifth input device (50-62, 74, 98) for distinguishing an signal which is effective at the transmitter station to output a program; and
- 50 an sixth processor (73) operatively connected to said sixth processor (73) for locating or identifying some portion of a program.
- 55 142. The transmitter station apparatus of claim 139, wherein said sixth input device (50-62, 74, 98) receives from a fourth remote station an instruct signal which is effective at the transmitter station to output said program at said fourth specific time.
- 56 143. The transmitter station apparatus of any one of claims 117-142, wherein said program input receiver (76, 78, 53-62) receives a signal that contains at least some of said program and contains embedded data that identifies said program or designates the starting point of some portion of said program or comprises a message associated with

- said program, said apparatus further comprising:
- a digital detector (34, 37, 38, 43 or 44 in any decoder) operatively connected to said program input receiver (76, 78, 53-62) for detecting data embedded in a signal.
 - 144.** The transmitter station apparatus of any one of claims 117-142, wherein a message associated with said program, that contains video, audio, or computer programming or a video, audio, or data file, is communicated to or stored at said program input receiver (76, 78, 53-62) prior to said first named specific line, said apparatus further comprising:
 - a seventh processor (73, 39J in any decoder) for processing one or more such messages.
 - 145.** The transmitter station apparatus of any one of claims 117-144, wherein a message that contains a command associated with said program is communicated to or stored at said program input receiver (76, 78, 53-62) prior to said first named specific line, said apparatus further comprising one of:
 - an eighth processor (39J in any decoder) for distinguishing a command in a message associated with a program; and
 - a first response controller (73, 39 in any decoder, 12 in 71) operatively connected to said tenth processor (39J in any decoder) for controlling some apparatus in response to such a command in a message.
 - 146.** The transmitter station apparatus of any one of claims 117-145, wherein a message that contains a motor-monitor segment associated with said program is communicated to or stored at said program input receiver (76, 78, 53-62), said apparatus further comprising one of:
 - an ninth processor (39J in any decoder) for distinguishing a motor-monitor segment in a message associated with a program; and
 - a tenth processor (in 71, 95) operatively connected to said eleventh processor (39J in any decoder) for assembling or storing motor files or monitor files that evidence the handling or transmitting of a program or a message associated with a program.
 - 147.** The transmitter station apparatus of any one of claims 117-146, wherein a message associated with said program that contains a header or formal field is communicated to or stored at said program input receiver (76, 78, 53-62), said apparatus further comprising:
 - an eleventh processor (39J in any decoder) for distinguishing the format, content, or end of some portion of a message associated with a program on the basis of a header or formal field.
 - 148.** The transmitter station apparatus of any one of claims 117-147, wherein a message associated with said program that contains an end of file signal or a processor interrupt is communicated to or stored at said program input receiver (76, 78, 53-62), said apparatus further comprising:
 - a signal detector (39F or 39H in any decoder) for detecting an end of file signal or communicating a processor interrupt associated with a broadcast or cablecast program; and
 - a twelfth processor (73, 39A in any decoder) operatively connected to said signal detector (39F or 39H in any decoder) for responding to a processor interrupt associated with a broadcast or cablecast program.
 - 149.** The transmitter station apparatus of any one of claims 117-148, further comprising:
 - a third computer (73) operatively connected to a transmitter (63, 87, 91 or 92) for generating and communicating a message that is to be associated with a program and contains some video, audio, or computer programming or a video, audio, or data file.
 - 150.** The transmitter station apparatus of any one of claims 117-149, further comprising:
 - a fourth computer (73) operatively connected to a transmitter (63, 87, 91 or 92) for generating some portion of a command and communicating said command in a message to be associated with a program.
 - 151.** The transmitter station apparatus of any one of claims 117-150, further comprising:
 - a fifth computer (73) operatively connected to a transmitter (63, 87, 91 or 92) for generating and communicating some portion of a motor-monitor segment to be associated with a program.
 - 152.** The transmitter station apparatus of any one of claims 117-151, further comprising:

- a sixth computer (73) operatively connected to a transmitter (63, 87, 91 or 92) for generating some part of a message having a specific format and to be associated with a program and for communicating said portion of a message with a header or formal field that designates said specific format.
- 153.** The transmitter station apparatus of any one of claims 117-152, further comprising:
- a seventh computer (73) operatively connected to said program input receiver (76, 78, 53-62) to a transmitter (63, 87, 91 or 92) for generating a message associated with a program and containing a processor interrupt.
 - 154.** The transmitter station apparatus of any one of claim 139 and claims 140-153 when appended to claim 139, further comprising:
 - an ninth selective transmission device (73 or 75) operatively connected to one or more of said input devices (50-62, 71, 73, 74, 98) and to said program input receiver (76, 78, 53-62) for communicating to said program input receiver a message to be associated with said program, one or more data that identify said program, one or more data that designate the starting point of some portion of said program, or a signal that is effective at the receiver station to instruct.
 - 155.** The transmitter station apparatus of any one of claims 117-154, wherein said program is communicated to and stored at said program input receiver (76, 78, 53-62) prior to said first named specific line, said apparatus (either comprising):
 - a second program input receiver (78, 53-62) operatively connected to a transmission device (73 or 75) for communicating a program to said first named program input receiver (76, 78, 53-62).
 - 156.** The transmitter station apparatus of claim 120 and any one of claims 121-155 when appended to claim 120, wherein said first named program input receiver (76, 78, 53-62) is said fourth memory (73) or recorder (76 or 78), said apparatus further comprising:
 - a second decoder (77, 79) operatively connected to a memory (75) or recorder (76 or 78) for decoding information coded in a stored signal;
 - A second control processor (39A in 77, 39B in 79, 73) for distinguishing a decoded stored signal which is effective at the transmitter station to instruct;
 - A ninth selective transmission device (39J in 77, 39I in 79) operatively connected to said second control processor (39I in 77, 39J in second decoder (77, 79) for communicating a transmitter instruct signal to a controller (73, 205C, 39 in any decoder) or computer (73); and
 - A third output controller (39J in 77, 39 in 79, 73) operatively connected to said ninth selective transmission device (39J in 77, 39I in 79) for controlling said ninth selective transmission device (39J in 77, 39 in 79) to communicate a transmitter instruct signal to a specific controller (73, 205C, 39 in any decoder) or computer (73).
 - 157.** The transmitter station apparatus of claim 156, further comprising:
 - A thirteenth processor (in 71, 73 in 39 of any decoder) operatively connected to a controller (73, 205C, 39 in any decoder) or computer (73) for distinguishing a specific decode (in 71, 77, 75, 80, B4, 88) or communicating a datum designating a specific program input receiver (76, 78, 53-62).
 - 158.** The transmitter station apparatus of claim 155 and any one of claim 156 or claim 157 when appended to claim 155, further comprising one of:
 - A first switch (75) operatively connected to said broadcast or cablecast transmitter (63, 87, 91, 92) or communicating signals selectively from said first named program input receiver (76, 78, 53-62) and said second program input receiver (78, 53-62); and
 - A second switch (75) operatively connected to said second program input receiver (76, 78, 53-62) or communicating signals selectively to said first named program input receiver (76 or 78) and said broadcast or cablecast transmitter (63, 87, 91, 92).
 - 159.** The transmitter station apparatus of claim 158, wherein said first switch (75) or said second switch (75) is controlled by said central controller (73).
 - 160.** The transmitter station apparatus of any one of claims 117-159, wherein said transmitter station includes a plurality of program input receivers (53-62) for receiving signals from one or more remote programming sources or a plurality

- of memories (73) or recorders (76 and 78) for storing signals or a plurality of broadcast or cablecast transmitters (83, 87, 91, 92), said apparatus further comprising:
 a matrix switch (39) in any decoder) capable of communicating a plurality of signals simultaneously.
161. The transmitter station apparatus of claim 160 when appended to claim 123, wherein said matrix switch (75) or digital switch (39) in any decoder) is controlled by said central controller (73).
162. The transmitter station apparatus of any one of claims 117-161, further comprising:
 a signal generator (82, 86, 90) operatively connected to said broadcast or cablecast transmitter (83, 87, 91, 92) for receiving said control signal and embedding said control signal in said information transmission.
163. The transmitter station apparatus of claim 162 when appended to claim 153, wherein said control signal is communicated to said signal generator (82, 86, 90) by any one of said third computer (73), said fourth computer (73), said fifth computer (73), said sixth computer (73), and said seventh computer (73).
164. The transmitter station apparatus of any one of claims 117-163, wherein said information transmission comprises a plurality of channels of television programming and/or radio programming, said apparatus further comprising:
 a plurality of modulators (83, 87, 91), each modulator (83, 87, 91) operatively connected to a program input receiver (76, 78, 53-62) for modulating a channel, and
 a multiplexing system (92) operatively connected to said broadcast or cablecast transmitter (83, 87, 91) for communicating an information transmission comprising a plurality of channels.
165. The transmitter station apparatus of any one of claims 117-164, wherein said transmitter station comprises one or more processor systems (71, 39 in any decoder) for processing signals that contain commands and program output information content, said apparatus further comprising:
- one or more transmitter sections (12 and 39 in each decoder of 71, 39 in each 39) for transmitting commands and/or program output information content selectively to one or more external receiver devices (72, 73, 97 in 71; 73 and 205C in 73);
 one or more receiver sections (1, 2, 3, 6, 27, 28, 29 in 71; 393, 390, 394 in 39) for receiving input of said commands and program output information content;
 one or more memory (8, 14, in 39 in 71; 39E, 39F, 39G, 39H, RAMs in 39) or recorder (20 in 71) sections for storing and communicating a control signal which at a receiver device (73) or recorder station (37) can operate to generate a receiver specific datum; and
 one or more control input sections (20 and each 39 in 71; 39E, 39F, 39G, 39H, RAMs in 39) or recorder (20 in 71) section, or causing said memory (8, 14, in 39 in 71; 39E, 39F, 39G, 39H, RAMs in 39) or recorder (20 in 71) section to communicate said control signal at a specific time.
166. The apparatus of claim 165, wherein any one of said one or more transmitter sections (12 and 39 in each decoder of 71; 39 in each 39), said one or more receiver sections (1, 2, 3, 6, 27, 28, 29 in 71; 39B, 39D, 39J in 39), said one or more memory (8, 14, in 39 in 71; 39E, 39F, 39G, 39H, RAMs in 39) or recorder (20 in 71) sections, and said one or more control input sections (20 and each 39 in 71; 39F, 39H, 39J in 39) comprises a plurality of processors (39B, 39D, 39J) on a single microchip (39, Fig. 3A).

Patentansprüche

- 50 1. Verfahren zur Verarbeitung von Signalen in einer Empfängerstation mit einem Mikrocomputer (205) und einer Ausgabevorrichtung (202M), um in der Ausgabevorrichtung eine kombinierte Ausgabe eines rundengeteilten oder kabelgesendeten Programms und eines empfänger spezifischen Datenelements abzugeben, wobei das Verfahren die folgenden Schritte umfaßt:
 (a) Empfangen (215) einer Informationsübertragung (202M), um in der Ausgabevorrichtung eine kombinierte Ausgabe eines rundengeteilten Programms und eines empfänger spezifischen Datenelements zu erzeugen, die ein Programm und ein oder mehrere Steuersignale umfaßt;
 (b) Wählen des empfänger rundengeteilten oder kabelgesendeten Programms aus der Informationsübertragung (202M), um eine spezifische Vorrichtung aus der Voltzahl von Prozessor- und/oder Controller (205) zu steuern;
- 55 11. Verfahren nach Anspruch 8, bei dem der Controller in der Lage ist, ein Interruptsignal an eine Prozessor- und/oder Controller-Vorrichtungen zu übermitteln, wobei das Verfahren den folgenden Schritt aufweist:
 Programmieren des Controllers, um eine spezifische Vorrichtung aus der Voltzahl von Prozessor- und/oder Controller (205) zu steuern;

troller-Vorrichtungen zu unterbrechen.

12. Verfahren nach einem der Ansprüche 8 bis 11, ferner mit den folgenden Schritten: Ermitteln eines Interruptsignals in der Informationsübertragung und Steuern des Controllers, um das ermittelte Interruptsignal an einen Prozessor oder Controller zu übermitteln.
13. Verfahren nach einem der Ansprüche 8 bis 12, bei dem als Antwort auf die Ermittlung des spezifischen Steuersignals in der Informationsübertragung der Mikrocomputer so organisiert wird, daß das empfängergerätspezifische Datenelement als Teil einer Serie von empfängergerätspezifischen Daten erzeugt wird und ein Prozessor-Interruptsignal in den Mikrocomputer eingegeben wird, um zu einer spezifischen Zeit die Übermittlung eines oder mehrerer spezifischer empfängergerätspezifischer Daten an die Ausgabevorrichtung zu ermöglichen.
14. Verfahren nach Anspruch 13, bei dem das Interruptsignal an den Mikrocomputer als Antwort auf ein zweites weiteres Steuersignal, das in der rundingssendeten oder kabelgesendeten Steuerinformation übertragen wird, ein gegeben wird und das Interruptsignal bewirkt, daß der Mikrocomputer die spezifische Speicherstelle loscht und ein erzeugtis empfängergerätspezifisches Datenelement an der spezifischen Speicherstelle ablegt, um eine nachfolgende Komplettierung des Ausgabezubildens.
15. Verfahren nach Anspruch 14, bei dem ein Steuersignal, das in der rundingssendeten oder kabelgesendeten Informationsübertragung ermittelt wird, bewirkt, daß der Mikrocomputer aufhält, einen oder mehrere empfängergerätspezifische Daten an die Ausgabevorrichtung zu übermitteln, und beginnt oder wiederbeginnt, diese Serie zu erzeugen.
16. Verfahren nach einem der Ansprüche 8 bis 12, ferner mit den folgenden Schritten: Ermitteln eines Steuerprogramms in der Informationsübertragung und Bewirken, daß der Controller, einen oder mehrere Empfängerstationen vorrichtungen entsprechend dem Steuerprogramm steuert.
17. Verfahren nach einem der vorliegenden Ansprüche, bei dem das empfängergerätspezifische Datenelement nicht automatisch an die Ausgabevorrichtung (202M) übermittelt wird, wenn das empfängergerätspezifische Datenelement an der Speicherstelle abgelegt wird und das Verfahren ferner die folgenden Schritte aufweist:
Ermitteln (203), in der Informationsübertragung, eines dritten weiteren Steuersignals, das so wirkt, daß der Mikrocomputer (205) anweisen wird, das empfängergerätspezifische Datenelement an den Speicherstelle an die Ausgabevorrichtung zu übermitteln, wodurch bewirkt wird, daß der Mikrocomputer (205) das empfängergerätspezifische Datenelement an die Ausgabevorrichtung (202M) übermittelt.
18. Verfahren nach Anspruch 13, ferner mit dem folgenden Schritt: Bestimmen (39), daß der Mikrocomputer nicht vorbereitet ist, ein erstes empfängergerätspezifisches Datenelement zu einer spezifischen Zeit an die Ausgabevorrichtung zu übermitteln, und anschließendes Bewirken (39A), daß der Mikrocomputer eine spezifische Computerprogrammsteuerung ausführt, um dadurch zu beginnen, ein nachfolgendes empfängergerätspezifisches Datenelement dieser Serie zu erzeugen.
19. Verfahren nach einem der vorliegenden Ansprüche, bei dem die Information, die im Mikrocomputer gespeichert ist, nutzergerätspezifische Daten aufweist und das Verfahren ferner den folgenden Schritt aufweist:
Weitergeben (203) von Aktualisierungsdaten an den Mikrocomputer (205), um dadurch zu bewirken, daß die gespeicherten Nutzerdaten aktualisiert werden, wodurch beim Erzeugen eines nachfolgenden empfängergerätspezifischen Datenelements die aktualisierten Nutzerdaten von dem Mikrocomputer verarbeitet werden.
20. Verfahren nach Anspruch 19, bei dem die Aktualisierungsdaten in der rundingssendeten oder kabelgesendeten Informationsübertragung ermittelt und von einem Decoder (290) weitergegeben werden.
21. Verfahren nach Anspruch 19, bei dem die Aktualisierungsdaten in einer Informationsübertragung empfangen werden, die eine Telefonübertragung umfaßt.
22. Verfahren nach Anspruch 21, bei dem die Empfängerstation automatisch die Telefonübertragung für eine oder mehrere Aktualisierungsdaten ausübt.
23. Verfahren nach einem der vorliegenden Ansprüche, ferner mit den folgenden Schritten: Speichern (200) von Information in der Empfängerstation, die festlegt, daß die Empfängerstation eine spezifische Informationsübertragung automatisch selektiv empfangen sollte, und selektives Empfangen (200), der Informationsübertragung einer Zahl von ähnlichen Empfängerstationen ist, die die gleiche Informationsübertragung empfangen, wobei das Gerät von der Empfängerstation abgeleitet wird.

sprechend der gespeicherten Information.

24. Verfahren nach Anspruch 23, bei dem als Antwort auf ein Freigabe-Siueursignal die Empfängerstation befähigt wird, das rundingssendete oder kabelgesendete Programm an zu empfangen, indem in dem Prozessor ein oder mehrere Computerprogrammumweilungen eingegeben (200) werden, die in der Lege sind die Empfängerstation zu steuern (200), um die rundingssendete oder kabelgesendete Informationsübertragung zu empfangen, das Programm zu wählen und die Steuernsignale zu emittieren.
25. Verfahren nach Anspruch 23 oder 24, ferner mit den folgenden Schritten: Empfangen (200, Fig. 2) und Speichern (200, Fig. 2) von Vorausinformation der Übertragung des spezifischen Programms.
26. Verfahren nach einem der vorliegenden Ansprüche, ferner mit den folgenden Schritten: Zusammenstellen von Aufzeichnungen (200, Fig. 2) in der Empfängerstation; Auswahl und/oder Verwendung von rundingssendeten oder kabelgesendeten Programmen, Steuersignalen und/oder Nutzerdaten aufzeichnen, und Übermitteln (200, Fig. 2) der Aufzeichnungen an eine entfernte Datennahmestation.
27. Verfahren nach einem der vorliegenden Ansprüche, ferner mit dem folgenden Schritt: Erhöhen (225), In einem Prozessor in der Empfängerstation, von Information der Reaktion eines Nutzers auf eine Ausgabe in der Ausgabevorrichtung (202M).
28. Verfahren nach Anspruch 27, ferner mit dem folgenden Schritt: Vorarbeiten (200, Fig. 2, oder 205) der Nutzeraktionen auf Antwort auf ein weiteres weiteres Steuersignal, das in der rundingssendeten oder kabelgesendeten Information als Antwort auf eine Eingabeinformation zu zusätzliche Antwortinformation zu erzeugen.
29. Verfahren nach Anspruch 27 oder 28, ferner mit dem folgenden Schritt: Übermitteln (200, Fig. 2) mindestens eines Teils der Eingabeinformation oder der zusätzlichen Antwortinformation an eine entfernte Datennahmestation.
30. Verfahren nach einem der vorliegenden Ansprüche, bei dem das rundingssendete oder kabelgesendete Programm oder mindestens einige der Steuersignale, die in der Informationsübertragung enthalten sind, verschlüsselt und mit einem Signal bezeichnete sind das eine verschlüsselte Übertragung anzeigt, und das Verfahren ferner den folgenden Schritt aufweist: Steuern (200, Fig. 2) eines Entschlüsselungsseit in der Empfängerstation, um das Programm und die verschlüsselten Steuersignale als Antwort auf eine Ermittlung des bestimmten Signals zu entschlüsseln.
31. Verfahren nach einem der vorliegenden Ansprüche, ferner mit dem folgenden Schritt: Speichern der empfängergerätspezifischen Information übertragung in einer Speichererweiterung (217, 255 oder 256) um die Abgabe der kombinierten Ausgabe zu einer Zeit zu ermöglichen, zu der das rundingssendete oder kabelgesendete Programm nicht von der Empfängerstation empfangen wird.
32. Verfahren nach einem der vorliegenden Ansprüche, bei dem die Ausgabevorrichtung eine oder mehrere aus der Gruppe ist, die aus einem Drucker (221) zum Ausgeben von gedruckter Information, einem Turgenerator (263) zum Ausgeben von Tönen, einer Videoausgabevorrichtung (202M) zum Ausgeben von Videoinformation, einer Videospeicherstation (217) zum Speichern von Videoinformation, einer Tonspachervorrichtung (255) zum Speichern von Toninformation und einem Zwischenhander (92) besteht.
33. Verfahren nach Anspruch 32, bei dem die Ausgabevorrichtung ein Fernsehmonitor (202M) ist, die spezifische Speicherstelle an Video-RAM ist und das empfängergerätspezifische Datenelement aus der Speicherstelle gelöscht wird, indem Information einer Wechselfarbe an der Speicherstelle abgelegt wird, und die Wechselfarbe lichtdurchlässig erscheint, wenn sie in dem Monitor in Kombination mit einem Zwischenhander (92) besteht.
34. Verfahren nach Anspruch 33, bei dem die spezifische Speicherstelle des Mikrocomputers, an der das empfängergerätspezifische Datenelement abgelegt wird, auf der Grundlage des Bodiments eines Farbenpunktes und einer skalaren Dimension für das empfängergerätspezifische Datenelement im Schritt des Erzeugens (205) des empfängergerätspezifischen Datenelements gewählt wird.
35. Verfahren nach einem der vorliegenden Ansprüche, bei dem die Empfängerstation eine Station aus einer Vielzahl von ähnlichen Empfängerstationen ist, die die gleiche Informationsübertragung empfangen, wobei das Gerät von der Empfängerstation abgeleitet wird.

36. Verfahren nach Anspruch 35, bei dem eine Zeitspanne, die den Empfang des spezifischen Steuereignals durch die Empfängerstationen und den Empfang der des dritten weiteren Steuereignals durch die Empfängerstationen bestimmt, ausreicht, daß jeder Empfängerstationenmikrocomputer den Schritt des Erzeugens beenden kann, bevor jeder Empfängerstationenmikrocomputer das erste weitere Steuesignal empfängt.

37. Empfängerstationengerät zur Verarbeitung von Signalen, um eine kombinierte Ausgabe eines rundgesendeten oder kabelgesendeten Programms und eines von einem empfänger spezifischen Computer erzeugten Datenelements abzugeben, wobei die Station eine Ausgabevorrichtung (202M) zum Abgeben des rundgesendeten oder kabelgesendeten Programms und anderer Information aufweist, wobei das Gerät umfaßt:

 - (a) einen Decoder (203) mit Einrichtungen zum:
 - (1) Empfangen einer Informationsübertragung, die ein rundgesendetes oder kabelgesendetes Programm und ein oder mehrere Steuareignisse umfaßt;
 - (2) Emittieren des Vorhandenseins von Steuereignissen in der Informationsübertragung; und
 - (3) Weitergeben der emittierten Steuesignale an einen Mikrocomputer (205);

wobei der Mikrocomputer (205) betriebsfähig mit der Ausgabevorrichtung (202M) und dem Decoder (203) verbunden ist, wobei der Mikrocomputer (205) eine spezifische Speicherstelle (PC-MicroKey) des Mikrocomputers (205) aufweist, die mit der Ausgabevorrichtung (202M) verbunden ist, zum Übermitteln von Daten, die an der spezifischen Speicherstelle (PC-MicroKey) des Mikrocomputers (205) gespeichert sind, an die Ausgabevorrichtung (202M) und der Mikrocomputer (205) so programmiert wird, daß die folgenden Schritte auf der Grundlage eines oder mehrerer spezifischer Steuersignale durchgeführt werden:

 - (1) Erzeugen eines empfänger spezifischen Datenelements durch Verarbeiten von Information, die in dem Mikrocomputer (205) gespeichert ist, als Antwort auf das Empfangen eines spezifischen Signals;
 - (2) Ablegen des empfänger spezifischen Datenelements an der spezifischen Speicherstelle (PC-MicroKey) des Mikrocomputers (205);
 - (3) Übermitteln des empfänger spezifischen Datenelements an der Speicherstelle an die Ausgabevorrichtung (202M); und nachfolgendes
 - (4) Löschen des Datenelements aus der spezifischen Speicherstelle (PC-MicroKey des Mikrocomputers 205), wodurch eine kombinierte Ausgabe des empfangenen rundgesendeten oder kabelgesendeten Programms und des empfänger spezifischen Datenelements in der Ausgabevorrichtung (202M) in der Zeitspanne zwischen dem Schritt des Ablegens des Datenelements an der Speicherstelle (PC-MicroKey des Mikrocomputers 205) und dem Schritt des Löschens des Datenelements aus der Speicherstelle (PC-MicroKey des Mikrocomputers 205) abgegeben wird.

38. Gerät nach Anspruch 37, bei dem die Ausgabevorrichtung eine Videoausgabevorrichtung (202M) und das ermittelte Steuesignal ein Signal ist, das den Mikrocomputer (205) so steuert, daß ein empfänger spezifisches Videodatenelement an der spezifischen Speicherstelle abgelegt wird, wobei das Gerät ferner einen Videoausgabespieldraht (PC-Microkey von 205) aufweist, der mit dem Mikrocomputer (205) und der Videoausgabevorrichtung (202M) verbunden ist, zum Übermitteln von Videoinformationen an die Videoausgabevorrichtung (202M).

39. Gerät nach Anspruch 37 oder 38, bei dem die Ausgabevorrichtung eine Tonausgabevorrichtung (203) und das ermittelte Steuesignal ein Signal ist, das den Mikrocomputer (205) so steuert, daß ein spezifisches Tonstattleine (Ton-FRM von 205), der mit dem Mikrocomputer (205) und der Tonausgabevorrichtung (203) verbunden ist, zum Übermitteln von Toninformationen an die Tonausgabevorrichtung (203) aufweist.

40. Gerät nach einem der Ansprüche 37 bis 39, ferner mit einem programmierbaren Controller (39 des Decoderiers 203), der mit dem Mikrocomputer (205) verbunden ist, zum Steuern des Verarbeiters, Erzeugens und/oder Ausgebens des Mikrocomputers (205) als Antwort auf Steuesignale, die in einer rundgesendeten oder kabelgesendeten Informationsübertragung enthalten werden.

41. Gerät nach Anspruch 40, bei dem der Controller (39 in Fig. 2a, 44 in Fig. 2b, 47 in Fig. 2c) betriebsfähig mit dem

42. Gerät nach Anspruch 41, bei dem der Steuerochip (39) ein Computiprogramm in einem gewöhnlichen Prozessor (35), CPU von 205) oder Controller (39, von 200) aufweist, wobei ein gewöhnlicher Prozessor (35), CPU von 205) oder Controller (39, von 200) eine Art und Weise der Identifizierung oder Baumitteilung eines Stauereignisses in der Informationsübertragung modifiziert, wobei das Gerät ferner ein selektives Übertragungsgerät (13 in Fig. 2D, 39 in Fig. 3A, 259 in Fig. 7) zum Übermitteln von Information, die in der Informationsübertragung ermittelt wird, an den gewählten Prozessor (35), CPU von 205) oder Controller (39, von 200) aufweist;

43. Gerät nach Anspruch 42, bei dem die selektive Übertragungs vorrichtung (13 in Fig. 2D, 39 in Fig. 3A, 259 in Fig. 7) ein Bus (13 in Fig. 2D), ein Matrixschalter (39) ist.

44. Gerät nach einem der Ansprüche 41 bis 43, wobei irgendeiner, nämlich der Controller (39), der Steuerochip (35) oder der Mikrocomputer (205) eine Variable von Prozessoren (35B, 35D, 39) auf einem einzigen Mikrochip (39, Fig. 3A) aufweist.

45. Gerät nach einem der Ansprüche 37 bis 44, bei dem der Mikrocomputer (205) eine Eingabe empfängt, die ein Computerprogramm und/oder mehrere Interruptsignale aufweist, und das empfänger spezifische Datenelement entsprechend dem Computerprogramm erzeugt oder die spezifische Speicherstelle als Antwort auf die eine oder mehrere Interruptsignale löst, wobei das Gerät ferner einen oder mehrere Puffer (P, 35A, 35C, 39C, in 205) oder Speicher (in 39B, in 39D, in 39J, 217, 217A) zum Speichern und Übermitteln des Computerprogramms an den Mikrocomputer (205) aufweist.

46. Gerät nach einem der Ansprüche 37 bis 45, bei dem der Prozessor (39A, 200) eine Steuerauflösung auf der Grundlage einer Aufzeichnung des Vorhandenseins oder Nichtvorhandenseins eines Programms oder eines empfänger spezifischen Datenelements übernimmt, wobei das Gerät ferner einen Bildschärfer (Bildschirmspeicher für die ersten SPAM-Vorbedingung und für die zweite SPAM-Vorbedingung in 39J, in 20, 14 oder 16 in 200)) zum Speichern einer oder mehrerer Aufzeichnungen des Vorhandenseins oder Nichtvorhandenseins eines Programms oder eines empfänger spezifischen Datenelements aufweist.

47. Gerät nach Anspruch 45, wenn dieser ein Anspruch 46, wobei der Controller (39 des Decodiefers 203) ein Interruptsignal in den Mikrocomputer (205) eingeht, um zu bewirken, daß der Mikrocomputer (205) zu einer spezifischen Zeit ein empfänger spezifisches Datenelement übermittelt.

48. Gerät nach einem der Ansprüche 37 bis 47, bei dem ein empfänger spezifisches Datenelement als Antwort auf eine Reaktion des Nutzers auf eine Ausgabe in dem Ausgabegerät (202M) ausgetragen wird, wobei das Gerät ferner aufweist: eine Eingabevorrichtung (202M) zum Eingeben von Information einer Reaktion eines Nutzers auf eine Ausgabe und einen Prozessor (200, C1) von 205), der betreibbar ist mit der Eingabevorrichtung (225) verbunden ist, zum Verarbeiten der eingegebenen Information einer Reaktion eines Nutzers.

49. Gerät nach einem der Ansprüche 37 bis 48, bei dem die Station an eine entfernte Station eine Aufzeichnung ausgibt, die die Verfügbarkeit, der Zweck und/oder die Verwendung eines Programms, eines Steuersignals oder einer kombinierten Ausgabe in der Empfängerstation oder eine gewisse Eingabe der Reaktion eines Nutzers auf eine kombinierte Ausgabe eines empfänger spezifischen Datenelements oder kabelgesendeten oder empfänger spezifischen Datenelements aufweist.

50. Gerät nach einem der Ansprüche 37 bis 49, bei dem das spezifische Steuersignal bewirkt, daß der Mikrocomputer (Mischer 3 gemäß Fig. 2) verbunden ist, zum Speichern von Information eines gewählten Programms und zum Empfangen von Information einer Zeit (Z), wobei das Gerät ferner eine Computerperipheriesteuergerätheheit (232, 256), die mit dem Mikrocomputer (205) verbunden ist, zum Speichern der aufzuhaltenden Daten aufweist.

51. Gerät nach einem der Ansprüche 37 bis 50, ferner mit einem Speicher (20 von 200), der mit einem Empfänger (Mischer 3 gemäß Fig. 2) verbunden ist, zum Speichern von Information eines gewählten Programms und zum

um zu bewirken, daß die Station das gewählte Programm zu der Zeit oder in der Frequenz empfängt.

52. Gerät nach einem der Ansprüche 37 bis 51, ferner mit einer Speichervorrichtung (217, 255, 256), die mit einem Empfänger (201, 215) oder einer Ausgabevorrichtung (202M) verbunden ist, zum Empfangen und Speichern, wodurch mindestens gewisse Informationen eines empfangenen Steuersignals und eines empfangenen Steuersignals oder eines empfänger spezifischen Datenelements für eine zielvorschobene Ausgabe an den Nutzer gespeichert wird.
53. Gerät nach einem der Ansprüche 37 bis 52, ferner mit einem Einschlüsseler oder Entwürfier (224), der mit einem Empfänger (201) verbunden ist, um ein Entschlüsselsignal oder Entwürfisignal der Information dieses empfangenen Programms oder eines empfangenen Steuersignals, das verschlüsselt oder verwordnet ist, zu ermöglichen.
54. Gerät nach einem der Ansprüche 37 bis 53, ferner mit einer beliebigen Übertragungsvorrichtung (258) zum Übermitteln des Programms von einem Empfänger (201, 215) oder einer Speicher vorrichtung (217, 217A) an eine Speicher vorrichtung (217, 217A) oder eine Ausgabevorrichtung (202M).
55. Gerät nach einem der Ansprüche 37 bis 54, bei dem die Information übertragung eine Mehrkanalübertragung ist, wobei das Gerät ferner einen Umsatzer (201) zum Empfangen und Umsetzen eines gewissen Abschnitts der Mehrkanalübertragung und zum Umsetzen eines gewissen Abschnitts der Mehrkanalübertragung in eine spezielle Ausgangsfrequenz aufweist.
56. Gerät nach einem der Ansprüche 37 bis 55, ferner mit einem Drucker (221) und einer Druckausgabedateicheiste (Druckpfeiler 205), die mit dem Mikrocomputer (205) und dem Drucker (221) verbunden ist, zur Übermittlung von Druckerkennung an den Drucker (221).
57. Gerät nach einem der Ansprüche 37 bis 56, bei dem das Programm ein Fernsehprogramm ist, wobei das Gerät ferner einen Fernseh zentner (215) zum Empfangen eines Fernsehsignals, das das Programm enthält, und einen Fernsehmonitor zum Ausgeben des Fernsehprogramms und des empfänger spezifischen Datenelements aufweist.
58. Gerät nach Anspruch 37 und einem der Ansprüche 39 bis 56, wobei das Programm ein Hörfunkprogramm ist, wobei das Gerät ferner einen Hörfunkzentrer (2019T) zum Empfangen eines Hörfunkprogramms und ein Lautsprechersystem (283) zum Ausgeben des Programms und des empfänger spezifischen Datenelements aufweist.
59. Verfahren zum Übermitteln eines Massenmediumprogrammmaterials an eine Vielzahl von Empfängerstationen, von denen jede abweist: einen Empfänger für rundgesendete oder kabelgebundene Programme (Tuner 215), eine Ausgabevorrichtung (202M), einen Steuerspieldiskret (Decoderar 203), einen Mikrocomputer (205) mit einer speziellen Speicherstation (PC-MicroKey das Mikrocompuiter 205), der in der Lage ist, an die Ausgabevorrichtung (202M) zu übermitteln, und wobei jede Empfängerstation gleichzeitig ist, das Vorhandensein eines oder mehrerer Steuersignale zu ermitteln, ein empfänger spezifisches Datenelement als Antwort auf das ermittelte spezifische Steuersignal zu erzeugen und in der Ausgabevorrichtung eine kombinierte Ausgabe des rundgesendeten oder kabelgesendeten Programms und des empfänger spezifischen Datenelements abzugeben, wobei das Verfahren das Übermitteln die folgenden Schritte aufweist:
- (1) Empfangen eines zu übertragenden Programms und Abgeben des Programms an einen Sonderrichter;
 - (2) Empfangen und Speichern eines Steuersignals, das in der Empfängerstation wirkt, um das empfänger spezifische Datenelement zu erzeugen; und
 - (3) Bewirken, daß das gespeicherte Steuersignal zu einer spezifischen Zeit an den Sonderrichter übermittelt wird, um dadurch eine Informationsübertragung, die das Programm und ein oder mehrere Steuersignale umfaßt, zu übertragen.
60. Verfahren nach Anspruch 59, bei dem die Informationsübertragung zur gleichen Zeit an zwei Stationen aus der Vielzahl der Empfängerstationen übertragen wird und jede der beiden Empfängerstationen ihre kombinierte Ausgabe des empfänger spezifischen Datenelementen oder kabelgesendeten oder kabelgebundenen Programms abgibt und ihr erzeugtes empfänger spezifisches Datenelement in der gleichen Zeitspanne in ihrer Ausgabevorrichtung (202M) abgibt.
61. Verfahren nach Anspruch 58, bei dem die Informationsübertragung zu verschiedenen Zeiten an zwei aus der Vielzahl von Empfängerstationen übertragen wird und jede der beiden Empfängerstationen ihre kombinierte Aus-

Gabe des empfänger gerundgesendeten oder kabelgesendeten Programms und ihr erzeugtes empfänger spezifisches Datenelement in einer anderen Zeitspanne in ihrer Ausgabevorrichtung (202M) abgibt.

62. Verfahren nach einem der Ansprüche 59 bis 61, bei dem eine Speicherstelle mit einem Computer zum Empfangen und Speichern gewisser Information des Steuersignals verbunden ist, wobei das Verfahren ferner die folgenden Schritte aufweist: Ermitteln eines Signals, das in der Sonderrichtung wirkt, um zu übertragen, und Erzeugen des Sonderrichtungssignals in den Computer, um dadurch zu bewirken, daß der Computer gewisse Information des Steuersignals erzeugt und die erzeugte Information an der Speicherstelle ablegt.
63. Verfahren nach Anspruch 62, ferner mit dem folgenden Schritt: Programmieren des Computers, um auf das Sender-Erzeugungssignal zu antworten, indem Information, die in dem Computer gespeichert ist, verarbeitet wird.
64. Verfahren nach Anspruch 62 oder 63, bei dem der Computer speziell Form- und Artikel dieser Übertragung als Antwort auf das Sender-Erzeugungssignal verarbeitet, ferner mit den folgenden Schritten: Eingaben der Form- und Artikel-Daten in den Computer.
65. Verfahren nach einem der Ansprüche 62 bis 64, das ferner umfaßt: Erzeugen eines gewissen Abschnitts eines Computerprogramms und eines Datamoduls als Antwort auf das Sender-Erzeugungssignal.
66. Verfahren nach einem der Ansprüche 59 bis 65, ferner mit den folgenden Schritten: Bewirken, daß eine Speicherstelle, die in der Lage ist, ein Computerprogramm zu speichern und zu übermitteln, ein Computerprogramm an einen Sonderrichter, um das Computerprogramm zu übertragen, um dadurch zu bewirken, daß mindestens ein Empfängerprogramm in einem Prozessor läuft und bewirkt, daß der Prozessor unter Steuerung des Computerprogramms Information erzeugt und ausgibt.
67. Verfahren nach Anspruch 66, ferner mit dem folgenden Schritt: Zusammestellen des gespeicherten und übermittelten Computerprogramms zu einer Nachricht mit einer Vielzahl von Segmenten, wobei das Computerprogramm sich in einem spezifischen Teil der Nachricht befindet und die Nachricht Information aufweist, die bewirkt, daß mindestens eine Empfängerstation des Computerprogramm in einem gewählten Prozessor aus einer Vielzahl von Prozessoren eingesetzt wird.
68. Verfahren nach Anspruch 66 oder 67, ferner mit den folgenden Schritten: Bewirken, daß eine Speicherstelle, die in der Lage ist, ein Anweisungs signal zu speichern und zu übermitteln, um das Anweisungs signal an einen Computer zu übertragen, um als Antwort darauf einen Abschnitt des Computerprogramms in dem Computer zu erzeugen.
69. Verfahren nach einem der Ansprüche 59 bis 68, bei dem die Sonderrichtung eine Vielzahl von Segmenten, wobei das Sonderrichter ein Ton- und/oder ein Daten signal, das von der Sonderrichtung übertragen wird, überträgt; wobei das Verfahren ferner den folgenden Schritt aufweist: Speichern des empfänger stationen einen oder mehrerer Signale, nämlich des Tono-, Ton- und/oder Daten signals, für eine Zeitspanne, während einer Übertragung des empfänger stationen einen oder mehrerer Signale, nämlich des Tono-, Ton- und/oder Daten signals, verzögert wird.
70. Verfahren nach einem der Ansprüche 59 bis 69, bei dem ein Controller das Wettbewerb an einen spezifischen empfänger stationen steuert, wobei das Verfahren ferner die folgenden Schritte aufweist: Ermitteln von eingebetteter Information in dem spezifischen empfänger stationen Signal und Steuern des Wettbewerb des spezifischen empfänger stationen auf der Grundlage der ermittelten eingebetteten Information.
71. Verfahren nach Anspruch 70, bei dem der Controller einen Schalter steuert, wobei das Verfahren ferner umfaßt: Steuern des Schalters, um Signale selektiv von einem oder mehreren Programmierbarempfängern und einem oder mehreren Speicherstellen an eine oder mehrere Speicherstellen oder einen oder mehrere Sender zu übertragen.
72. Verfahren nach Anspruch 71, bei dem die Sonderrichtung eine Vielzahl von Nachrichten an eine Station aus der Vielzahl von Empfängerstationen überträgt, um die eine Empfängerstation zu steuern, um ihre kombinierte Ausgabe des Programms und ihrer empfänger spezifischen Daten elements in ihrer Ausgabevorrichtung auszugeben, wobei das Verfahren ferner die folgenden Schritte aufweist: Übermitteln eines Signals, das eine Nachricht aus der Vielzahl von Nachrichten enthielt, von einem Programmierungssubkomppfänger an einen Speicherstelle und nachfolgend-

des Übermitteln des Signals, das die eine Nachricht aus der Vielzahl von Nachrichten enthält, von dieser Speicherstelle an einen Sender.

73. Verfahren nach einem der Ansprüche 70 bis 72, bei dem die Senderstation mindestens ein Programm speichert, wobei das Verfahren lerner die Schritte aufweist: Empfangen des Programms in einem Programmmeingabebevorrichtung. Übermitteln des Programms an eine Speichervorrichtung und Speichern des Programms in der Speichervorrichtung mit einem Anweisungssignal, das in der Senderstation so wirksam ist, daß einer nähmlich der Computer oder der Controller gesiezt wird.

74. Verfahren nach Anspruch 73, ferner mit den folgenden Schritten: Ermitteln des Anweisungssignals und Übermitteln des Anweisungssignals an einen, nähmlich den Computer oder den Controller.

75. Verfahren nach Anspruch 71 oder nach einem der Ansprüche 72 bis 74, wenn diese vom Anspruch 71 abhängig sind, lerner mit dem folgenden Schritt: Steuern des Schalters auf der Grundlage des Vorhandenseins oder Nichtvorhandenseins eines Anweisungssignals, das mit einem Programm gespeist wird.

76. Verfahren nach einem der Ansprüche 59 bis 75, bei dem die Senderstation eine Vielzahl von Programmmeingabeempfängern aufweist, wobei das Verfahren lerner die folgenden Schritte aufweist: Verarbeiten von Signalen, die in der Vielzahl von Programmmeingabeempfängern empfangen werden, Übermitteln von Steuerinformation als Antwort auf ein eingeschaltbares Datenelement und Steuern des Weitergebiens eines Signals, das in einem speziellischen Empfänger aus der Vielzahl von Programmmeingabeempfängern empfangen wird, auf der Grundlage der übermittelten Steuerinformation.

77. Verfahren nach einem der Ansprüche 59 bis 76, bei dem das Programm und das Empfänger-Erzugungssignal vor einem oder mehreren entkoppelten Stationen kommand empfangen werden, wobei das Verfahren lerner die folgenden Schritte aufweist: Verarbeiten eines Signals, das von der einen oder mehreren entkoppelten Stationen kommt und amplifiziert wird und Steuern der Sender oder das Empfänger-Erzugungssignal an einen Computer zu übermitteln, und zwar auf der Grundlage von Information in dem verarbeiteten empfangenen Signal.

78. Verfahren nach einem der Ansprüche 59 bis 77, lerner mit den folgenden Schritten: Empfangen des Programms in einem Empfänger in der Empfängerstation, Übermitteln des Programms von dem Empfänger an die Speicherstation und Speichern des Programms an der Speicherstelle für eine Zeitspanne vor dem Übermitteln des Programms an einen Sender.

79. Verfahren nach Anspruch 78, ferner mit den folgenden Schritten: Empfangen des Programms in einem gewählten Empfänger aus einer Vielzahl von Empfängern in der Sende station und Übermitteln des Programms von dem gewählten Empfänger an einen Sender.

80. Verfahren nach einem der Ansprüche 78 bis 79, lerner mit den folgenden Schritten: Übertragen des Programms in einem gewählten Sender aus einer Vielzahl von Sendern und Übermitteln des Programms an den gewählten Sender.

81. Verfahren nach einem der Ansprüche 59 bis 80, bei dem ein Schalter empfangene Signale selektiv von mindestens einem Empfänger und mindestens einer Speicherstelle an einen Sender übermittelt, wobei das Verfahren lerner die folgenden Schritte aufweist: Eingehen eines Signals, das in der Senderstation so wirkt, daß seine Übermittlung angewiesen wird, und Steuern des Schalters, um ein empfangenes Signal von einem Empfänger an eine Speicherstelle zu übermitteln, und zwar als Antwort auf das Anweisungssignal.

82. Verfahren nach Anspruch 81, wenn dieser von Anspruch 62 abhängt, ist, wobei das empfangene Signal das Sender-Erzugungs signal enthält, wobei das Verfahren lerner den folgenden Schritt aufweist: nachfolgendes Übermitteln mindestens eines Teils des Sender-Erzugungssignals von der Speicherstelle an die zweite Speicherstelle.

83. Variante nach einem der Ansprüche 59 bis 83, bei dem das empfangene Signal das Programm enthält, wobei das Verfahren lerner den loggenden Schritt aufweist: Steuern des Schalters, um das Programm an einen Sender zu übermitteln.

84. Variante nach einem der Ansprüche 59 bis 83, bei dem eine Vielzahl von Signalen von einer oder mehreren

5 85. Verfahren nach Anspruch 84, wenn dieser von Anspruch 70 abhängig ist, wobei eines oder mehrere des gewählten Signals ein Signal ist, das in der Sende station so wirkt, daß einer, nähmlich der Computer oder der Controller angewiesen wird, wobei das Verfahren lerner den folgenden Schritt aufweist: Bewirken, daß eine Speicherstelle das Anweisungssignal vor der speziellischen Zeit übermittelt, und Steuern des einen, nähmlich des Computers oder des Controllers als Antwort auf das Anweisungssignal.

10 86. Verfahren nach einem der Ansprüche 59 bis 85, bei dem eine Vielzahl von Signalen von einer oder mehreren entkoppelten Stationen empfangen wird und mindestens eines in der Sende station gespeichert wird und ein Signal aus der Vielzahl von empfangenen Signalen nach einem Plan beliebstäßig ist, wobei das Verfahren lerner die folgenden Schritte aufweist: Programmieren der Sende station, um den Plan zu speichern und bewirken, daß der Sender entsprechen dem Plan überträgt.

15 87. Verfahren nach Anspruch 86, ferner mit dem folgenden Schritt: Bewirken, daß die Sende stationen entsprechend dem Plan erzeugt.

20 88. Verfahren nach Anspruch 86 oder 87, lerner mit dem folgenden Schritt: Absimmen eines Empfängers oder Steuern einer Satelliten-Erstation, um ein Signal entsprechend dem Plan zu empfangen.

25 89. Verfahren nach einem der Ansprüche 59 bis 88, ferner mit den folgenden Schritten: Empfangen einer Informationsantragung von einer entkoppelten Station, Ermitteln, in der Informationssubersetzung, eines Anweisungssignals, das in der Sende station so wirkt, daß ein Anweisungssatz ausgeleuchtet wird, Laden eines Anweisungssatzes in einen Computer als Antwort auf das Anweisungssignal und, auf der Grundlage des Anweisungssatzes, Wählen von Information, die in der Empfängerstation zu verarbeiten ist, oder übermitteln von Information, die mit dem Programm im Zusammenhang steht.

30 90. Verfahren nach einem der Ansprüche 59 bis 89, bei dem ein Controller eine Speicherstelle steuert, um einen Sender ein gewähltes Steuerrignal zu übermitteln, wobei das Verfahren lerner die folgenden Schritte aufweist: Ermitteln eines Signals, das in der Sende station so wirkt, daß eine Übertragung angezeigt wird, und Ergeben des Signals in den Controller, um dadurch zu bewirken, daß die Speicherstelle ein gewähltes Steuerrignal übermittelt.

35 91. Verfahren nach Anspruch 90, lerner mit dem folgenden Schritt: Programmieren des Controllers, um auf das Signal zu antworten, indem eine gewählte Speicherstelle gesteuert wird, um ein Steuerrignal zu übermitteln, oder indem bewirkt wird, daß eine Speicherstelle ein gewähltes Steuerrignal übermittelt.

40 92. Verfahren nach Anspruch 90 oder 91, bei dem das Übertragungsanweisungssignal in einer von einer entkoppelten Station übertragenen rundgesendeten oder kabelgesendeten Informationübertragung empfangen wird.

45 93. Verfahren nach einem der Ansprüche 90 bis 92, ferner mit den folgenden Schritten: Speichern eines Signals, das in der Empfänger station so wirkt, daß angewiesen wird, und Steuern der Speicherstelle, um ein gewähltes Steueringssignal in einer geplanten Zeit entsprechend dem Anweisungssignal zu übermitteln.

50 94. Verfahren nach einem der Ansprüche 90 bis 93, lerner mit dem folgenden Schritt: Speichern des Signals an der Speicherstelle mit dem Programm.

55 95. Verfahren nach einem der Ansprüche 90 bis 94, ferner mit den folgenden Schritten: Steuern einer Speicherstelle, um das Programm als Antwort auf ein erstes Anweisungssignal an einen Sender zu übermitteln, und Steuern einer Speicherstelle, um ein gewähltes Steuerrignal als Antwort auf ein zweites Anweisungssignal zu übermitteln.

60 96. Verfahren nach Anspruch 95, lerner mit den folgenden Schritten: Ermitteln eines Steuerrsignals, das von der Speicherstelle übermittelt wird, und Programmieren eines Controllers, um auf ein der Speicherstelle übermitteltes Steuerrsignal zu antworten.

65

97. Verfahren nach einem der Ansprüche 90 bis 95, ferner mit dem folgenden Schritt: Erhalten eines Anweisungssignals in das Programm, um dadurch einen Controller in die Lage zu versetzen, in einer Zeit, in der das Programm übermittelt wird, auf das eingegebene Anweisungssignal zu antworten.
- 5 98. Verfahren nach Anspruch 64 und nach einem der Ansprüche 65 bis 97, wenn diese von Anspruch 64 abhängig sind, wobei das Sender-Erzeugungssignal oder die Formel- und Artikel-Daten in einer von einer entfernt stehenden Station übertragenen rundgesendeten oder Kabelfestsendeten Informationsoberleitung empfangen wurden, wobei das Verfahren ferner die folgenden Schritte aufweist: Empfangen eines Anwesungssignals von einer entfernt stehenden Station und Übertragen der Formel- und Artikel-Information als Antwort darauf.
- 10 99. Verfahren nach einem der Ansprüche 59 bis 98, ferner mit den folgenden Schritten: Speichern eines Signals, das in der Übertragungsstation so wirkt, daß eine Erzeugung angewiesen wird, und Steuern eines Computers, um vor der spezifischen Zeit entsprechend dem gespeicherten Anweisungssignal gespeicherte Information zu verarbeiten.
- 15 100. Verfahren nach einem der Ansprüche 59 bis 99, ferner mit den folgenden Schritten: Speichern und Übertragen, an eine Empfängerstation, von Daten, die eine Übertragungszeit oder einen Übertragungskanal oder eine gewisse Spurte eines spezifischen Programms festlegen, und nachfolgendes Übertragen des Programms entsprechend den festgelegten Daten, um dadurch zu ermöglichen, daß die Empfängerstation das Programm wählt und speichert oder wählt und ausgibt.
- 20 101. Verfahren nach einem der Ansprüche 59 bis 100, ferner mit den folgenden Schritten: Übertragen, an eine Empfängerstation, eines Steuersignals, um zu bewirken, daß die Empfängerstation sich nach einem Parallelverarbeitungssystem ausrichtet und gewisse Information, die mit einem in einer runde sendenden oder kabelgesendeten Informationsübertragung übertragenen Programm oder Statuswahlt im Zusammenhang steht, auswählt und in einen Mikrocomputer, abgibt und bewirkt, daß der Mikrocomputer gespeicherte Information verarbeitet und als Antwort auf die eingegebene Information eine Ausgabe erzeugt.
- 25 102. Verfahren nach Anspruch 100 oder 101, ferner mit den folgenden Schritten: Übermitteln, an einen Signalgenerator, von Daten, die eine Übertragungszeit oder einen Übertragungskanal oder eine gewisse Spurte eines spezifischen Programms festlegen, oder eines Stauraumsignals und Antilogs der Stauraumsignals an einen speziellen Teil einer runde sendenden oder kabelgesendeten Informationsübertragung oder Anfügen der übermittelten Daten oder des übermittelten Stauraumsignals an eine runde sendende oder kabelgesendete Informationsübertragung in einer Nachricht ihres spezifischen Formats.
- 30 103. Verfahren nach einem der Ansprüche 59 bis 102, ferner mit den folgenden Schritten: Bewirken, daß eine Speicherstelle, die in der Lage ist, ein Signal zu speichern und zu übermitteln, das in der Empfängerstation so wirkt, daß sie als Quelle dient, aus der ein zu erzeugendes empfänger spezifisches Datenelement zu wählen ist, das Signal an einen Sender übermittelt, um das Signal zu übertragen, um dadurch zu bewirken, daß mindestens eine Empfängerstation ein zu erzeugendes empfänger spezifisches Datenelement wählt.
- 35 104. Verfahren nach einem der Ansprüche 59 bis 104, ferner mit den folgenden Schritten: Bewirken, daß eine Speicherstelle, die in der Lage ist, ein Signal zu speichern und zu übermitteln, das in der Empfängerstation so wirkt, daß es als Quelle dient, aus der ein zu erzeugendes empfänger spezifisches Datenelement zu wählen ist, das Signal an einen Sender übermittelt, um das Signal zu übertragen, um dadurch zu bewirken, daß mindestens eine Empfängerstation ein zu erzeugendes empfänger spezifisches Datenelement wählt.
- 40 105. Verfahren nach Anspruch 105, bei dem das Signal, das in der Empfängerstation so wirkt, daß es als Quelle dient, vor dem Empfänger-Erzeugungssignal übertragen wird, wodurch mindestens eine Empfängerstation in dem Quellsignal empfangene Daten speichert und ein empfänger spezifisches Datenelement erzeugt, indem die gespeicherten Daten verarbeitet werden.
- 45 106. Verfahren nach Anspruch 105, bei dem das Signal, das in der Empfängerstation so wirkt, daß es als Quelle dient, vor dem Empfänger-Erzeugungssignal übertragen wird, wodurch mindestens eine Empfängerstation in dem Quellsignal empfangene Daten speichert und ein empfänger spezifisches Datenelement erzeugt, indem die gespeicherten Daten verarbeitet werden.
- 50 107. Verfahren nach einem der Ansprüche 59 bis 106, ferner mit den folgenden Schritten: Bewirken, daß eine Speicherstelle, die in der Lage ist, ein Signal zu speichern und zu übermitteln, das in der Empfängerstation so wirkt, daß ein Kombinieren bestand, um das Signal zu übermitteln, um das Signal zu übermitteln, um das Signal zu übermitteln, um dadurch zu bewirken, daß mindestens eine Empfängerstation das Kombinieren ihres erzeugten empfänger spezifischen Datenelements zu einer spezifischen Zeit bindet.
- 55 108. Verfahren nach einem der Ansprüche 59 bis 107, ferner mit den folgenden Schritten: Bewirken, daß eine Speicherstelle, die in der Lage ist, ein Signal zu speichern und zu übermitteln, das in der Empfängerstation so wirkt, daß kombiniert wird, das Signal an einen Sender übermittelt, um das Signal zu übertragen, um dadurch zu bewirken, daß mindestens eine Empfängerstation eine kombinierte Ausgabe des empfänger runden sendenden oder kabelgesendeten Programms und das empfänger spezifische Datenelements in ihrer Ausgabevorrichtung zu einer spezifischen Zeit abgibt.
- 60 109. Verfahren nach einem der Ansprüche 59 bis 108, ferner mit den folgenden Schritten: Bewirken, daß eine Speicherstelle, die in der Lage ist, ein Signal zu speichern und zu übermitteln, das in der Empfängerstation so wirkt, daß ein erzeugtes empfänger spezifisches Datenelement so wirkt, daß ein Signal an einen Sender übermittelt wird, um das Signal zu übertragen, um dadurch zu bewirken, daß mindestens eine Empfängerstation eine Ausgabe des empfänger runden sendenden oder kabelgesendeten Programms und das empfänger spezifische Datenelements in ihrer Ausgabevorrichtung zu einer spezifischen Zeit abgibt.
- 65 110. Verfahren nach einem der Ansprüche 59 bis 109, ferner mit dem folgenden Schritt: Ermitteln eines Signals, das in der Sanderstation so wirkt, daß es eine Erzeugung anweist, in einem Signal, nämlich einem Fernsehsignal oder einem Rundfunksignal oder an einer Speicherstelle, die ein Programm, nämlich die Fernsehprogramm oder ein Funkprogramm speichert.
- 70 111. Verfahren nach einem der Ansprüche 59 bis 110, bei dem die Empfängerstation eine entlarm stehende Zwischen-senderstation ist, die Ausgabevorrichtung (202M) ein Sender (63, 87, 91, 92) ist, der Mikrocomputer (205) eine autonome Steuereinheit (73) für die Zwischen-senderstation ist und die spezifische Speicherstelle ein Programm-gesetz zum Übertragungs-Speicher ist, wobei das Verfahren ferner die Schritte umfaßt:
- (1) Empfangen eines oder mehrerer Anweisungssignale, die in der Teilnehmerstation so wirken, daß ein Computer (73, 205) oder Prozessor (in 71, 200, 39J) angewiesen wird in bezug auf eine Art und Weise des Empfangens oder der Darbietens von Fernsehprogramm abgleich oder des Funktionsleitens auf der Grundlage einer Zuschauerreaktion auf ein Fernsehprogramm- oder Computerausgababteilung und des Abgebens des einen oder mehreren Anweisungssignale an einen Sender;
- (2) Empfangen eines oder mehrerer Steuesignale, die in der entlarm stehenden Zwischen-senderstation so wirken, daß sie den einen oder mehreren Anweisungssignale ausführen oder übermitteln; und
- (3) Bewirken, daß einer oder mehrere Steuesignale vor der spezifischen Zeit an den Sender übermittelt werden,
- um dadurch eine Informationsübertragung zu übertragen, die einen oder mehrere Anweisungssignale und ein oder mehrere Steuergänge aufweist.
- 75 112. Verfahren nach einem der Ansprüche 59 bis 111, bei dem die Empfängerstation eine entlarm stehende Zwischen-senderstation ist, die Ausgabevorrichtung (202M) ein Sender (63, 87, 91, 92) ist, der Mikrocomputer (205), eine automatische Steuereinheit (73) für die Zwischen-senderstation ist und die spezifische Speicherstelle ein Programm-gesetz auf der Grundlage einer Nutzerreaktion auf eine Ausgabe, die dem Programm im Zusammenhang steht, und des Abgebens des einen oder mehrerer Anweisungssignale an den Sender vor der spezifischen Zeit;
- (3) Empfangen eines oder mehrerer Steuesignale, die in der entlarm stehenden Zwischen-senderstation so wirken, daß das Programm oder mehrere Anweisungssignale an den Sender vor der spezifischen Zeit; und Abgeben des einen oder mehreren Steuesignale an einen Sender vor der spezifischen Zeit;

- (4) Empfangen eines Plans, der in der emittierten Zwischensendersitzung so wirkt, daß das Programm und das eine oder mehrere Anweisungszeichen übertragen werden, und Abgeben des Plans an einen Sender vor der spezifischen Zeit.
- 113 Verfahren nach einem der Ansprüche 59 bis 112, bei dem eine Sendersitzung von einer Teilnehmerstation gewisse Information einer Reaktion eines Teilnehmers auf ein Fernsehprogramm oder eine Computerausgabedarstellung empfängt, wobei das Vorhaben mindestens einen der folgenden Schritte aufweist:
- Übertragen, an die Teilnehmerstation, eines Computerprogramms, das gewisse Information einer Reaktion eines Teilnehmers auf ein Fernsehprogramm oder eine Computerausgabedarstellung verarbeitet;
 - Definieren einer Variablen eines Anweisungssignals der ein Fraktionsanteil einer Fraktion eines Teilnehmers auf einen gewissen Teil eines Ausweisungssignals einer Fraktion gegeben ist;
 - Übertragen eines gewissen Teils eines Fernsehprogramms oder eines Ausweisungssignals auf der Grundlage einer Fraktion eines Teilnehmers auf ein Fernsehprogramm oder eine Computerausgabedarstellung.
- 114 Verfahren nach einem der Ansprüche 59 bis 113, ferner mit den folgenden Schritten: Bewirken, daß eine Sendersitzung das Programm überträgt, und Bewirken, daß eine zweite Sendersitzung überträgt, das in der Empfängersitzung so wirkt, daß das empfänger spezifische Datenelement erzeugt oder ein Datenmodul übertragen wird, das in der Empfängersitzung als eine Quelle eines empfänger spezifischen Datenelements dazu dient, auszuwählen und zu erzeugen.
- 115 Verfahren nach einem der Ansprüche 59 bis 114, bei dem das Programm über Satelliti an eine Teilnehmerstation übertragen wird und bewirkt wird, daß eine zweite Sendersitzung so wirkt, daß das Dienstursprung ist oder ein Datenmodul, das mit dem Programm in Zusammenhang steht, an die Teilnehmerstation rückzusenden oder kabel zu senden.
- 116 Verfahren nach einem der Ansprüche 59 bis 115, ferner mit dem folgenden Schritt: Übertragen einer Vielzahl von Programmen und einer oder mehrerer Signale, die in der Empfängersitzung so wirken, daß ein Wart analysiert oder ein Plan erzeugt wird, um dadurch zu bewirken, daß mindestens eine Teilnehmerstation auf der Grundlage seines potentiellen Wertes für einen Teilnehmer ein Programm aus der Reihe von Programmen wählt oder zwei oder mehrere Programme in einer empfänger spezifischen Reihenfolge ausgibt.
- 117 Empfängersitzungsgerät zum Verarbeiten von Signalen und zum Übermitteln von Massenmedium Programm materialien, um in jeder aus einer Vielzahl von Empfängerstationen eine kombinierte Ausgabe eines rundgesendeten oder kabel gesendeten Programms und eines empfänger spezifischen computerisierten Datenelements darzubieten, wobei jede der Empfängerstationen eine Ausgabevorrichtung (202M) aufweist zum Empfangen und zum Abgeben des rundgesendeten oder kabel gesendeten Programms und anderer Information, wobei die Station auch einen Mikrocomputer (205) mit einer speziellen Speicherstelle (PC-Microkey das Mikrocomputers 205) aufweist, die betriebsfähig mit der Ausgabevorrichtung (202M) verbunden ist, zum Steuern einer zweiten selektiven Übertragungseinrichtung (202M) verbunden ist, zum Speichern und Abgeben von Information an die Ausgabevorrichtung (202M), wobei das Sendersitzungsgerät aufweist:
- einen Rundfunk- oder Kabelsender (83, 87, 91 oder 92) zum Übermitteln, an eine Vielzahl von Empfängerstationen, einer Informationsübertragung, die ein Programm und ein oder mehrere Steuersignale aufweist;
 - einen Programmleitungsämpfänger (76, 78, 53 bis 62), verbunden mit dem Sender (83, 87, 91 oder 92) verbunden ist, zum Übermitteln des Programms an den Sender (83, 87, 91 oder 92);
 - einen Speicher (73) oder eine Aufzeichnungseinrichtung (76 oder 78), die betriebsfähig mit dem Sender (83, 87, 91 oder 92) verbunden ist, zum Speichern und Übermitteln eines Steuersignals, das in der Empfängerstation so wirkt, daß das empfänger spezifische Datenelement erzeugt wird; und
 - eine Eingabevorrichtung (98, 74, 50 bis 62), die betriebsfähig mit dem Speicher (73) oder der Aufzeichnungseinrichtung (76 oder 78) verbunden ist, um zu bewirken, daß der Speicher (73) oder die Aufzeichnungseinrichtung (76 oder 78) das Steuersignal in einer spezifischen Zeit an den Sender (83, 87, 91 oder 92) übermittelt, um dadurch das Programm und das Steuersignal an die Empfängerstationen zu übermitteln und zu bewirken, daß jede Station aus der Vielzahl der Empfängerstationen das Programm in ihrer Ausgabevorrichtung (202M) abgibt;
- 118 Sendersitzungsgerät nach Anspruch 117, bei dem die Sendersitzung an die Vielzahl von Empfängerstationen ein erstes senderspezifisches Datenelement überträgt und mindestens eine Station aus der Vielzahl von Empfängerstationen gewisse Information eines empfänger spezifischen Datenelements auf der Grundlage des ersten senderspezifischen Datenelements darbietet, wobei das Gerät ferner aufweist:
- ein zweiten Speicher (73) oder eine zweite Aufzeichnungseinrichtung (71 oder 78), die betriebsfähig mit dem Sender (83, 87, 91 oder 92) verbunden ist, zum Speichern und Übermitteln eines senderspezifischen Datenelements, das in der Empfängerstation gewisser Information eines empfänger spezifischen Datenelements dient.
- 119 Sendersitzungsgerät nach Anspruch 117, bei dem die Sendersitzung an die Vielzahl von Empfängerstationen ein zweites senderspezifisches Datenelement überträgt und mindestens eine Station aus der Vielzahl von Empfängerstationen das zweite senderspezifische Datenelement in ihrer Ausgabevorrichtung (202M) abgibt, wobei das Gerät ferner aufweist:
- einen dritten Speicher (73) oder eine dritte Aufzeichnungseinrichtung (76 oder 78), die betriebsfähig mit dem Sender (83, 87, 91 oder 92) verbunden ist, zum Speichern und Übermitteln gewisser Daten, die in der Empfängerstation gewisser Information eines empfänger spezifischen Datenelements dienen.
- 120 Sendersitzungsgerät nach einem der Ansprüche 117 bis 119, bei dem die Eingabevorrichtung den ersten Voraus signal angibt, das danach in der Sendersitzung zu der spezifischen Zeit so wirkt, daß der zuerst genannte Speicher (73) oder die zuerst genannte Aufzeichnungseinrichtung (76 oder 78) an den Sender (83, 87, 91 oder 92) ausgegeben wird, wobei das Gerät ferner aufweist:
- einen ersten Prozessor (73), der betriebsfähig mit der Eingabevorrichtung (50 bis 62, 74, 98) verbunden ist, zum Unterscheiden eines Voraussignals;
 - einen ersten Speichercontroller (73, 205C in 73), der betriebsfähig mit dem ersten Prozessor (73) verbunden ist, zum Steuern eines Speichers (73) oder einer Aufzeichnungseinrichtung (76 oder 78), um ein Odd mehrere Voraussignale zu speichern; und
 - einen vierten Speicher (73) oder eine vierte Aufzeichnungseinrichtung (76 oder 78), der bzw die betriebsfähig mit dem ersten Controller (73, 205C in 73) verbunden ist, zum Speichern des ersten Voraussignals.
- 121 Sendersitzungsgerät nach einem der Ansprüche 117 bis 120, bei dem die Eingabevorrichtung (98, 74, 50 bis 62) einen Anweisungssignal angibt, das in der Sendersitzung so wirkt, daß der zuerst genannte Speicher (73) oder die zuerst genannte Aufzeichnungseinrichtung (76 oder 78) zu der spezifischen Zeit an den Sender (83, 87, 91 oder 92) abgegeben wird, wobei das Gerät ferner aufweist:
- einen ersten Steuoprozessor (33, 73), der betriebsfähig mit der Eingabevorrichtung (98, 74, 50 bis 62) verbunden ist, zum Unterscheiden eines Signals, das in der Sendersitzung so wirkt, daß angekündigt wird, und einen ersten Ausgabecontroller (73, 205C in 73, 39 in jedem Decoder), der betriebsfähig mit dem ersten Steuoprozessor (33) verbunden ist, zum Ausgeben eines Steuersignals, das so wirkt, daß ein Speicher (73) oder eine Aufzeichnungseinrichtung (76 oder 78) ausgegeben wird.
- 122 Sendersitzungsgerät nach einem der Ansprüche 117 bis 121, ferner mit mindestens einem, nämlich:
- einem ersten selektiven Übertragungsvorrichtungscontroller (73), der betriebsfähig mit dem Programmleitungsämpfänger (76, 78, 53 bis 62) verbunden ist, zum Steuern einer ersten selektiven Übertragungsvorrichtung (76, 78, 53 bis 62) vor einer spezifischen Zeit zu übermitteln; und
 - einem zweiten selektiven Übertragungsvorrichtungscontroller (73), der betriebsfähig mit dem Rundfunk- oder Kabelseiter (83, 87, 91, 92) verbunden ist, zum Steuern einer zweiten selektiven Übertragungsvorrichtung (73, 75, 78, 78), um eines oder mehrere Signale aus einem oder mehreren Speichern (73) und/oder Aufzeichnungseinrichtungen (76 oder 78) zu einer spezifischen Zeit zu übermitteln.
- 123 Sendersitzungsgerät nach einem der Ansprüche 117 bis 122, ferner mit:
- einem zentralen Controller (73), der betriebsfähig mit einem verbunden ist, nämlich mit dem Programmleitungsämpfänger (76, 78, 53 bis 62) oder dem Rundfunk- oder Kabelseiter (83, 87, 91, 92), zum Steuern der Übertragung, an diesen einen einen gewissen Abschnitt des Programms, eines Teils einer Nachricht, die mit dem Programm im Zusammenhang steht, eines Datenelements oder mehrerer Daten, die das Programm identifizieren, gewisser Vorausformulierung des Programms, eines Datenelements oder mehreren Daten, die den Anfangs-

EP 0 382 764 B1

punkt eines gewissen Abschnitts des Programms bezeichneten, oder eines Signals, das das Programm bezeichneten und in der Empfängerstation so wirkt, daß angewiesen wird.

124. Empfängersortierungsgerät nach Anspruch 123, ferner mit einem, nämlich:
einem Taktgeber, der betriebsfähig mit dem zentralen Controller (73) verbunden ist; oder
einer zweiten Eingabevorrichtung (98, 74, 50 bis 62), die betriebsfähig mit dem zentralen Controller (73) ver-
bunden ist, zum Eingeben einer oder mehrerer Taktsteueranweisungen.

125. Sondersortierungsgerät nach Anspruch 123 oder 124, ferner mit einem, nämlich:
einem zweiten Prozessor (73, in 71, in jedem Decoder), der betriebsfähig mit dem zentralen Controller (73)
verbunden ist, zum Unterscheiden eines Taktsteuersignals oder einer Zeit, zu der ein Signal weitergegeben
ist, das so wirkt, daß angewiesen wird;

15 einem zweiten Speichercontroller (73), der betriebsfähig mit dem zentralen Controller (73) verbunden ist, zum
Steuern eines gewählten Speichers (73) oder einer gewählten Aufzeichnungsseinrichtung (76 oder 78), um ein
Vorauseigentum zu speichern, das so wirkt, daß angewiesen wird; oder
einem liniären Speicher (73) oder einer liniären Aufzeichnungsseinrichtung (76 oder 78), der bzw. die betriebs-
fähig mit dem zentralen Controller (73) verbunden ist, zum Speichern von zwei oder mehreren Signalen in
einer Pufferfolge.

126. Sondersortierungsgerät nach einem der Ansprüche 119 oder 120 bis 125, wann diese von Anspruch 119 abhängig
sind, ferner mit:
einem ersten Computer (73), der betriebsfähig mit einem, nämlich dem zweiten Speicher (73) oder der zwei-
ten Aufzeichnungsseinrichtung (76 oder 78) bzw. dem dritten Speicher (73) oder der dritten Aufzeichnungsseinrich-
tung (76 oder 78) verbunden ist, zum Empfangen von Formel- und Artikel-Daten und zum Ausgeben eines gewis-
sen Abschnitts eines Datenelements an den einen Speicher (73) oder die eine Speicher (73) oder die eine Aufzeichnungsseinrichtung (76 oder 78).

127. Sondersortierungsgerät nach einem der Ansprüche 117 bis 126, bei dem ein Teil des Stauraums Formel- und-
Artikel-diese-Übertragung-Information ist, wobei das Gerät ferner aufweist:
einen zweiten Computer (73), der betriebsfähig mit dem zuerst genannten Speicher (73) oder der zuerst
genannten Aufzeichnungsseinrichtung (76 oder 78) verbunden ist, zum Ausgeben von Formel- und Artikel-Daten-
Übertragungsinformation als Antwort auf das Anweisungssignal, das in der Sondersortierungsstation so wirkt;

128. Sondersortierungsgerät nach einem der Ansprüche 120 und 121 bis 127, wenn diese von Anspruch 120 abhängig
sind, wobei ein Signal, das das Programm enthält, ein codiertes Anweisungssignal ergibt, das in der Sondersortierungs-
station so wirkt, daß die zuerst genannte Speicher (73) oder die zuerst genannte Aufzeichnungsseinrichtung (76 oder 78) an
den Sender (83, 87, 91 oder 92) ausgegeben wird, wobei das Gerät ferner aufweist:

129. Sondersortierungsgerät nach Anspruch 128, wenn dieser von Anspruch 122 abhängig ist, wobei die Sondersortierungs-
station, zum Decodieren von Information, die in einem Signal codiert ist, das ein Programm enthält;
eine direkte selektive Übertragungsvorrichtung (in 39, in 71), die betriebsfähig mit dem ersten Decoder (in
71) verbunden ist, zum Übermittlung einer vorrichtung (in 39, in 71), die betriebsfähig mit dem ersten Decoder (in
71) verbunden ist, zum Übermittlung einer vorrichtung (in 39, in 71), die betriebsfähig mit dem ersten Steuero-
prozessor (in 39, in 71) verbunden ist, zum Übermittlung einer vorrichtung (in 39, in 71), die betriebsfähig mit dem ersten Steuoprozessor
gewissen Abschnitten des Signals, der das Programm enthält, an die Empfängerstation verzögert wird, wobei das
Gerät ferner aufweist:

130. Sondersortierungsgerät nach Anspruch 128, wenn dieser von Anspruch 122 abhängig ist, wobei die Sondersortierungs-
station den ersten selektiven Übertragungsvorrichtungscontroller (73) aufweist und der Decoder (in 71, 77, 79), ein
Datenelement oder mehrere Daten decodiert, die in der Empfängerstation so wirken, daß eine Übermittlung eines
gewissen Abschnitts des Signals, der das Programm enthält, an die Empfängerstation verzögert wird, wobei das
Gerät ferner aufweist:

131. Sondersortierungsgerät nach Anspruch 128, wenn dieser von Anspruch 122 abhängig ist, wobei die Sondersortierungs-
station, zum Übermittlung eines Datenelements oder mehrerer Daten an den ersten Steuoprozessor
(in 39, in 71) verbunden ist, zum Übermittlung einer vorrichtung (in 39, in 71), die betriebsfähig mit dem ersten Steuoprozessor
(in 39, in 71) verbunden ist, zum Übermittlung einer vorrichtung (in 39, in 71), die betriebsfähig mit dem ersten Steuoprozessor
gewissen Abschnitten des Signals, der das Programm enthält, an den ersten selektiven Übertragungsvorrichtungscontroller

EP 0 382 764 B1

(73), eines Signals, das so wirkt, daß angewiesen wird.

132. Sondersortierungsgerät nach einem der Ansprüche 117 bis 129, bei dem die Eingabevorrichtung (98, 74, 50 bis 62)
einen ersten Empfänger (50 bis 62, 71, 73) aufweist zum Empfangen einer entfernt stehenden Station, eines
Signals, daß in der Empfängerstation so wirkt, daß angewiesen wird.
- 5 133. Sondersortierungsstation nach einem der Ansprüche 117 bis 130, bei dem der erste Computer (73) oder der
zweite Computer (73) eine gewisse Ausgabe als Antwort auf ein Anweisungssignal erzeugt, das in der Sondersortierungs-
station so wirkt, daß erzeugt wird, wobei das Gerät ferner aufweist:
- 10 einen sechsten Speicher (73) oder eine sechste Aufzeichnungsseinrichtung (76 oder 78) zum Speichern eines
Anweisungssignals, das in der Empfängerstation so wirkt, daß erzeugt wird; und
eine dritte Eingabevorrichtung (73, 98, in 71), die betriebsfähig mit dem sechsten Speicher (73) oder der
sechsten Aufzeichnungsseinrichtung (76 oder 78) verbunden ist, um zu bewirken, daß der sechste Speicher
(73) oder die sechste Aufzeichnungsseinrichtung (76 oder 78) in einer zweiten spezifischen Zeit ein Anwei-
sungssignal ausgibt, das in der Sondersortierungsstation so wirkt, daß erzeugt wird; und
eine sechste selektive Übertragungsvorrichtung (73), die betriebsfähig mit dem sechsten Speicher (73) oder
der sechsten Aufzeichnungsseinrichtung (76 oder 78) verbunden ist, zum Empfangen und Weiterleiten eines
oder mehrerer Anweisungssignale.
- 20 134. Sondersortierungsgerät nach Anspruch 131, ferner mit:
einem dritten Prozessor (73), der betriebsfähig mit der zweiten Eingabevorrichtung (73, 98, in 71) und dem
zweiten Speichercontroller (73) verbunden ist, zum Unterscheiden eines Anweisungssignals, das in der Empfän-
gerstation so wirkt, daß erzeugt wird, und zum Bewirken, daß der zweite Speichercontroller (73) den soeben
bestimmte Anweisungssignal zu speichern.
- 25 135. Sondersortierungsgerät nach Anspruch 131 oder 132, bei dem die zweite Eingabevorrichtung (73, 74, 98, in 71) von
der zweiten Sondersortierungsstation das Anweisungssignal empfängt, das in der Sondersortierungsstation so wirkt, daß
erzeugt wird.
- 30 136. Sondersortierungsgerät nach einem der Ansprüche 131 bis 133, ferner mit:
einem SPAM-Controller (205C in 73, 39 in jedem Decoder), 12 in 71, der betriebsfähig mit einem spezi-
ellen Computer (73) verbunden ist, zum Steuern des speziellen Computers (73), um die Computerprogramm
oder ein Datenmodul entsprechend dem Anweisungssignal, das in der Sondersortierungsstation so wirkt, daß erzeugt
wird, zu erzeugen oder auszugeben.
- 35 137. Sondersortierungsgerät nach einem der Ansprüche 128 bis 134, bei dem der Programmablaufpläne (76, 78,
53 bis 62) ein codiertes Anweisungssignal er gibt, das mit dem Programm empfangen wird und in der Empfän-
gerstation so wirkt, daß erzeugt wird, wobei das Gerät ferner aufweist:
- 40 eine siebente selektive Übertragungsvorrichtung (in 71, in 77, in 79), die betriebsfähig mit dem ersten Deco-
dierer (in 71, 77, 79) verbunden ist, zum Empfangen und Weiterleiten eines decodierten Signals; und
einen vierten Prozessor (73, in 71, in 77, in 79), der betriebsfähig mit der siebten selektiven Übertragungs-
vorrichtung (in 71, in 77, in 79) verbunden ist, zum Unterscheiden einer Vorrichtung, an die ein Signal wahr-
zugeben ist, das in der Sondersortierungsstation so wirkt, daß angewiesen wird.
- 45 138. Sondersortierungsgerät nach einem der Ansprüche 117 bis 125, bei dem die Sondersortierungsstation ein oder mehrere Signale
Oberträgt, die in der Empfängerstation so wirken, daß angewiesen wird, daß die spezifische Speicherstelle ein
empfängerspezifisches computererzeugtes Datenelement kombiniert oder zu kombinieren aufhält oder löscht,
wobei das Gerät ferner aufweist:
- 50 eine viele Eingabevorrichtung (50 bis 62, 74, 98), die betriebsfähig mit dem Rundfunk- oder Kabelsender
(83, 87, 91 oder 92) verbunden ist, zum Übermitteln einer oder mehreren Signale, die in der Sondersortierungsstation so
wirkt, daß angewiesen wird.
- 55 139. Sondersortierungsgerät nach Anspruch 136, bei dem die dritte entfernt stehende Station die eine oder mehrere Si-
gnale übermittelt, die in der Sondersortierungsstation so wirken, daß angewiesen wird, wobei das Gerät ferner aufweist:
- 60

- einen zweiten Empfänger (50 bis 62; 71; 73), der betriebsfähig mit einer selektiven Übertragungsvorrichtung (73; 75, in 71; 39 in jedem Decodierer) verbunden ist, zum Empfangen von einer an einem stehenden Station, eines oder mehrerer Signale, die in der Empfängerstation so wirken, daß angewiesen wird.
- 6 138.Senderstationengerät nach Anspruch 136 oder 137, ferner mit:
- einem siebenten Speicher (73) oder einer siebenten Aufzeichnungseinrichtung (76 oder 78), der bzw. die betriebsfähig mit einer selektiven Übertragungsvorrichtung (73; 75, in 71; 39 in jedem Decodierer) verbunden ist, zum Speichern eines oder mehrerer Signale, die in der Empfängerstation so wirken, daß angewiesen wird; und
- 10 einen fünften Eingabeverrichtung (50 bis 62; 74; 98), die betriebsfähig mit dem sechsten Speicher (73) oder der siebten Aufzeichnungseinrichtung (76 oder 78) verbunden ist, zum Bewirken, daß der siebente Speicher (73) oder die siebente Aufzeichnungseinrichtung (76 oder 78) in einer spezifischen Zeit an einer Rundfunk- oder Kabelsender (83; 87; 91 oder 92) eine oder mehrere Signale ausgibt, die in der Empfängerstation so wirken, daß angewiesen wird.
- 15 139.Empfängerstationengerät nach einem der Ansprüche 117 bis 138, bei dem der Programmeingabeempfänger (75; 78; 53 bis 62) ein Speicher (73) oder eine Aufzeichnungseinrichtung (76 oder 78) ist, in dem bzw. der mindestens ein Teil des Programms gespeichert wird, wobei das Gerät ferner aufweist:
- 20 eine sechste Eingabeverrichtung (50 bis 62; 74; 98), die betriebsfähig mit dem Programmeingabeempfänger (75; 78; 53 bis 62) verbunden ist, zum Bewirken, daß der Programmeingabeempfänger (76; 78; 53 bis 62) beginnt, das Programm an den Rundfunk- oder Kabelsender (83; 87; 91 oder 92) zu einer vierten spezifischen Zeit auszugeben.
- 25 140.Senderstationengerät nach Anspruch 139, ferner mit:
- einem achtten Speicher (73) oder einer achten Aufzeichnungseinrichtung (76 oder 78) zum Speichern eines Datumslements oder mehrerer Daten, die den Anfangspunkt eines Abschnitts eines Programms bezeichnen; und
- 30 einem zweiten Ausgabedekoder (73; 205C in 73; 39 in jedem Decodierer, 12 in 71), der betriebsfähig mit dem achtten Speicher (73) oder dem Programmeingabeempfänger (76; 78; 53 bis 62) verbunden ist, zum Steuern des Programmeingabeempfängers (76; 78; 53 bis 62), um die Ausgabe eines Abschnitts eines Programms am Anfang dieses Abschnitts zu beginnen.
- 35 141.Empfängerstationengerät nach Anspruch 139, bei dem die sechste Eingabeverrichtung (50 bis 62; 74; 98) ein Anweisungssignal erübrig, das in der Empfängerstation so wirkt, daß das Programm zu der vierten spezifischen Zeit ausgegeben wird, wobei das Gerät ferner eins aufweist, nämlich:
- 40 einen fünften Prozessor (73), der betriebsfähig mit der Unteren Eingabeverrichtung (50 bis 62; 74; 98) verbunden ist, zum Unterscheiden eines Signals, das in der Senderstation so wirkt, daß ein Programm ausgegeben wird; oder
- 45 einen sechsten Prozessor (73), der betriebsfähig mit dem sechsten Prozessor (73) verbunden ist, zum Lokalisieren oder Identifizieren eines gewissen Teils eines Programs.
- 50 142.Senderstationengerät nach Anspruch 139, bei dem die sechste Eingabeverrichtung (50 bis 62; 74; 98) von einer vierten entfernt stehenden Station ein Anweisungsdesignal empfängt, das in der Senderstation so wirkt, daß das Programm zu der vierten spezifischen Zeit ausgegeben wird.
- 55 143.Senderstationengerät nach einem der Ansprüche 117 bis 142, bei dem der Programmeingabeempfänger (76; 78; 53 bis 62) ein Signal empfängt, das mindestens einen Teil des Programms und eingesetzte Daten enthält, die das Programm identifizieren oder den Anfangspunkt eines gewissen Abschnitts des Programms festlegen oder eine Nachricht, die mit dem Programm im Zusammenhang steht, umfassen, wobei das Gerät ferner aufweist: einen Digitaldekoder (34; 37; 38; 43 oder 44 in jedem Decodierer), der betriebsfähig mit dem Programmeingabeempfänger (76; 78; 53 bis 62) verbunden ist, zum Ermitteln von Daten, die in einem Signal eingesetzt sind.
- 60 144.Senderstationengerät nach einem der Ansprüche 117 bis 143, bei dem eine Nachricht, die mit dem Programm im Zusammenhang steht, und Vdeo-, Ton- oder Computerprogramm oder eine Video-, Ton- oder Datendatei verbunden ist, wobei das Gerät ferner aufweist:
- 65 einen ersten Programmeingabeempfänger (76; 78; 53 bis 62) übermittelt wird oder von der zuerst genannten spe-

zifischen Zeit in diesem gespeichert wird, wobei das Gerät ferner aufweist:

einen siebten Prozessor (73; 39) in jedem Decodierer zum Verarbeiten einer oder mehrerer solcher Nachrichten.

6 145.Senderstationengerät nach einem der Ansprüche 117 bis 144, bei dem eine Nachricht, die einen Belehr enthält, der mit dem Programm im Zusammenhang steht, an den Programmeingabeempfänger (76; 78; 53 bis 62) übermittelt wird oder von der zuerst genannten spezifischen Zeit in diesem gespeichert wird, wobei das Gerät ferner eins aufweist, nämlich:

einen achtten Prozessor (39) in jedem Decodierer (73; 39) zum Unterscheiden eines Belehrs in einer Nachricht, die mit einem Programm im Zusammenhang steht; oder einen siebten Antihackcontroller (73; 39 in jedem Decodierer, 12 in 71), der betriebsfähig mit dem zehnten Prozessor (39) in jedem Decodierer verbunden ist, zum Stauen eines gewissen Geräts als Antwort auf einen Belehr in einer Nachricht.

10 146.Senderstationengerät nach einem der Ansprüche 117 bis 145, bei dem eine Nachricht, die ein Nutzungsmessungs-kontrollegerät anhält, das mit dem Programm im Zusammenhang steht, an den Programmeingabeempfänger (76; 78; 53 bis 62) übermittelt wird oder in diesem gespeichert ist, wobei das Gerät ferner eins aufweist, nämlich:

einen neunten Prozessor (39) in jedem Decodierer) zum Unterscheiden eines Nutzungsmessungskontroll-segments in einer Nachricht, die mit einem Programm im Zusammenhang steht; oder einen zehnten Prozessor (in 71; 96, der betriebsfähig mit dem alten Prozessor (39) in jedem Decodierer) verbunden ist, zum Zusammensetzen oder Speciellen von Nutzungsmessungsdaten oder Überwachungs-daten, die die Benutzung oder Übertragung eines Programms oder einer Nachricht, die mit einem Programm im Zusammenhang steht, nachzuweisen.

15 147.Senderstationengerät nach einem der Ansprüche 117 bis 146, bei dem eine Nachricht, die mit dem Programmeingabeempfänger (76; 78; 53 bis 62) übermittelt wird oder in diesem gespeichert ist, wobei das Gerät ferner eins aufweist:

20 einen neuen Prozessor (39) in jedem Decodierer zum Unterscheiden eines Nutzungsmessungskontroll-segments in einer Nachricht, die mit einem Programm im Zusammenhang steht; oder einen zehnten Prozessor (in 71; 96, der betriebsfähig mit dem alten Prozessor (39) in jedem Decodierer) verbunden ist, zum Zusammensetzen oder Speciellen von Nutzungsmessungsdaten oder Überwachungs-daten, die die Benutzung oder Übertragung eines Programms oder einer Nachricht, die mit einem Programm im Zusammenhang steht, nachzuweisen.

25 148.Senderstationengerät nach einem der Ansprüche 117 bis 147, bei dem eine Nachricht, die mit dem Programm im Zusammenhang steht und die einen Kopi oder in Formfeld anhält, an den Programmeingabeempfänger (76; 78; 53 bis 62) übermittelt wird oder in diesem gespeichert ist, wobei das Gerät ferner eins aufweist:

30 einen alten Prozessor (39) in jedem Decodierer zum Unterscheiden des Formats, Inhalts oder Endes eines gewissen Abschnitts einer Nachricht, die mit dem Programm im Zusammenhang steht, auf der Grundlage eines Kopiés oder Formfelds.

35 149.Senderstationengerät nach einem der Ansprüche 117 bis 147, bei dem eine Nachricht, die mit dem Programm im Zusammenhang steht und das Dateiendesignal oder ein Prozessor-interrupt enthält, an den Programmeingabeempfänger (76; 78; 53 bis 62) übermittelt wird oder in diesem gespeichert ist, wobei das Gerät ferner aufweist:

40 einen Signaledektor (39F oder 39H in jedem Decodierer) zum Ermitteln eines Datelandodesignale oder zum Übermitteln eines Prozessor-interrupts, das mit einem Rundfunk- oder Kabel programm im Zusammenhang steht; und einen zehnten Prozessor (73; 39 in jedem Decodierer), der betriebsfähig mit dem Signaledektor (39F oder 39H in jedem Decodierer) verbunden ist, zum Antworten auf ein Prozessor-interrupt, das mit einem Rundfunk- oder Kabel programm im Zusammenhang steht.

45 149.Senderstationengerät nach einem der Ansprüche 117 bis 148, ferner mit:

einem dritten Computer (73), der betriebsfähig mit einem Sender (83; 87; 91 oder 92) verbunden ist, zum Erzeugen und Übermitteln einer Nachricht, die mit einem Programm in Zusammenhang zu bringen ist und gewisse Video-, Ton- oder Computerprogrammo oder Video-, Ton- oder Datendateien enthält.

50 150.Senderstationengerät nach einem der Ansprüche 117 bis 149, ferner mit:

einem vierten Computer (73), der betriebsfähig mit einem Sender (83; 87; 91 oder 92) verbunden ist, zum Erzeugen eines gewissen Abschnitts eines Belehrs und zum Übermitteln des Belehrs in einer Nachricht, die mit einem Programm in Zusammenhang zu bringen ist.

55 151.Senderstationengerät nach einem der Ansprüche 117 bis 150, ferner mit:

dinem fünften Computer (73), der betriebsfähig mit dem Sender (83; 87; 91 oder 92) verbunden ist, zum Erzeugen und Übermitteln eines gewissen Abschnitts eines Nutzungsmessungskontrollsegments, das mit einem Programm in Zusammenhang zu bringen ist.

- | | |
|-----|---|
| 152 | Senderstationsgerät nach einem der Ansprüche 117 bis 151, ferner mit:
einem sozialen Computer (73), der betriebsfähig mit einem Sender (83, 87, 91 oder 92) verbunden ist, zum Erzeugen eines gewissen Teils einer Nachricht, die ein spezielles Format aufweist und mit einem Programm in Zusammenhang zu bringen ist, und zum Übermitteln des Abschnitts einer Nachricht mit einem Kopf oder Formatfeld, das spezifische Formate bezeichnet. |
| 153 | Senderstationsgerät nach einem der Ansprüche 117 bis 152, ferner mit:
einem sozialen Computer (73), der betriebsfähig mit dem Programmabgebempfänger (76, 78, 53 bis 62) verbunden ist, zum Übermitteln, an den Programmabgebeempfänger, einer Nachricht, die mit dem Programm in Zusammenhang steht und ein Prozessor-Interrupt enthält. |
| 154 | Senderstationsgerät nach einem der Ansprüche 139 und 140 bis 153, wenn diese von Anspruch 139 abhängig sind, ferner mit:
einer achtigen seltsamken Übertragungswichtung (73 oder 75), die betriebsfähig mit einem oder mehreren Eingaberichtungen (50 bis 62, 71, 73, 74, 98) und mit dem Programmabgebeempfänger (76, 78, 53 bis 62) verbunden ist, zum Übermitteln, an den Programmabgebeempfänger, einer Nachricht, die mit dem Programm in Zusammenhang steht und ein Prozessor-Interrupt enthält. |
| 155 | Senderstationsgerät nach einem der Ansprüche 117 bis 154, bei dem das Programmmeingebe-empfänger (76, 78, 53 bis 62) übermittelt wird oder vor der zuerst genannten spezifischen Zeit in diesem gespe- cherten wird, wobei das Gerät ferner aufweist:
einen zweiten Programmabgebeempfänger (78, 53 bis 62), der betriebsfähig mit der Übertragungswor- chtung (73 oder 75) verbunden ist, zum Übermitteln eines Programms an den zuvor genannten Programmmeingebe-empfänger (76, 78, 53 bis 62). |
| 156 | Senderstationsgerät nach Anspruch 120 oder einem der Ansprüche 121 bis 155, wenn diese von Anspruch 120 abhängig sind, wobei der zuerst genannte Programmabgebeempfänger (76, 78, 53 bis 62) vierter Speicher (73), oder die vierte Aufzeichnungseinrichtung (76 oder 78), wo bei das Gerät ferner aufweist:
einzen zweiten Decoder (77, 79), der betriebsfähig mit einem Speicher (73) oder einer Aufzeichnungsein- richtung (78 oder 78) verbunden ist, zum Decodieren von Information, die in einem gespeicherten Signal codiert ist; |
| 157 | Senderstationsgerät nach Anspruch 120 oder einem der Ansprüche 121 bis 155, wenn diese von Anspruch 120 abhängig sind, wobei der zuerst genannte Programmabgebeempfänger (76, 78, 53 bis 62) zum Unterscheiden eines decodierten gespeicherten Signals, das in der Empfängerstation so wirkt, daß angewiesen wird,
eine neuartige selektive Übertragungswichtung (39 in 77, 39 in 79, 73) in die, die betriebsfähig mit dem zweiten Steu- erprozessor (39 in 77, 39 im zweiten Decoder (77, 79)) verbunden ist, zum Übermitteln eines Sandor- Anweisungssatzes an einen Controller (73, 205C, 39). In jedem Decoder (73) und
einen dritten Ausgabecontroller (39 in 77, 39 in 79, 73), der betriebsfähig mit der neuen selektiven Übertra- gungswichtung (39 in 77, 39 in 79) verbunden ist, zum Steuern der neuen selektiven Übertragungswor- chtung (39 in 77, 39 in 79), um die Sendete Amplitude anzustellen an einen speziifischen Controller (73, 205C, 39 in jedem Decoder) oder Computer (73) zu übermitteln. |
| 158 | Senderstationsgerät nach Anspruch 155 oder nach einem der Ansprüche 156 oder 157, wenn diese von Anspruch 155 abhängig sind, ferner mit einem, nämlich:
einem dreizehntn Prozessor (71, 73, 79 jedes Decoder), der betriebsfähig mit einem Controller (73, 205C, 39 in jedem Decoder) oder Computer (73) verbunden ist, zum Unterscheiden eines speziifischen Decoder (71, 77, 79, 80, 84) oder zum Übermitteln eines Datenelementes, das einen speziifischen Pro- grammabgebeempfänger (76, 78, 53 bis 62) bezeichnet. |

(39, Fig. 3A) au/wieist

Revendications

5. 1. Procédé de traitement de signaux au niveau d'une station de récepteur comportant un micro-ordinateur (205) et un dispositif de sortie (202M) afin de délivrer au niveau du dispositif de sortie une sorte combinée constituée par un programme de radiodiffusion ou de diffusion par câble à partir de l'émission d'information au récepteur, les procédés comprenant les étapes de:
10. (a) réception (215) d'une émission d'information comprenant un programme et un ou plusieurs signaux de commande;
- (b) sélection dudit programme de radiodiffusion ou de diffusion par câble à partir de l'émission d'information et transfert de celui-ci sur le dispositif de sortie (202M) en vue d'une délivrance à l'utilisateur;
- (c) détection (203) d'un signal de commande spécifique dans l'émission d'information et passage dudit signal de commande spécifique détecté au micro-ordinateur (205); et
- (d) commande (205) dudit micro-ordinateur sur la base du signal de commande spécifique, ladite étape de commande comprenant:
20. (1) la génération (205) d'une donnée spécifique au récepteur en traitant une information qui est stockée dans said micro-ordinateur;
- (2) le placement (205) de ladite donnée en un emplacement de mémoire spécifique du micro-ordinateur (PC-Microkey) du micro-ordinateur (205);
- (3) la communication (205) de ladite donnée spécifique au récepteur au niveau dudit emplacement de mémoire audi dispositif de sortie (202M); et ensuite
25. (4) la mise à zéro (205) de ladite donnée dudit emplacement de mémoire spécifique de telle sorte que la sorte combinée constituée par ledit programme de radiodiffusion ou de diffusion par câble (202M) pendant la période temporelle entre ladite étape de placement de ladite donnée au niveau dudit emplacement de mémoire et ladite étape de remise à zéro de ladite donnée audi emplacement de mémoire.
2. Procédé selon la revendication 1, dans lequel, avant le placement de ladite donnée spécifique au récepteur au niveau de l'emplacement de mémoire spécifique, le dispositif de mémoire au niveau duquel ladite donnée spécifique au récepteur est placée est remis à zéro.
3. Procédé selon la revendication 1, dans lequel une ou plusieurs données spécifiques au récepteur supplémentaires sont communiquées automatiquement (205) audi dispositif de sortie (202M) à la suite de ladite donnée spécifique au récepteur.
4. Procédé selon l'une quelconque des revendications précédentes, dans lequel l'étape de génération d'une donnée spécifique au récepteur en traitant une information qui est stockée dans le micro-ordinateur est réalisée en exécutant (205) un programme ordinateur stocké dans la mémoire du micro-ordinateur afin de traiter ladite information stockée, et le procédé comprend en outre l'étape de:
45. détection (203) d'une émission d'information d'un premier signal de commande supplémentaire qui sera à charger le programme d'ordinateur dans la mémoire du micro-ordinateur (205).
5. Procédé selon la revendication 4, dans lequel l'émission d'information incorpore le programme d'ordinateur.
6. Procédé selon la revendication 4, dans lequel le premier signal de commande supplémentaire sera à donner instruction au micro-ordinateur de rechercher un module de logiciel dans un périphérique de mémoire (202).
50. 7. Procédé selon l'une quelconque des revendications précédentes, dans lequel la sortie combinée dudit programme de radiodiffusion ou de diffusion par câble (205) a de ladite donnée spécifique au récepteur est délivrée au niveau du dispositif de sortie en tant que partie d'une série de sorties combinées et les étapes de communication de ladite donnée spécifique au récepteur et de remise à zéro de l'emplacement de mémoire spécifique sont réalisées en réponse à un ou plusieurs signaux de commandes.
55. 8. Procédé selon l'une quelconque des revendications précédentes, dans lequel le traitement, la génération d'au moins un signal de commande de transmission de l'émission d'information qui est stockée dans l'émission en sortie dudit micro-ordinateur sont commandés par un contrôleur programmable en réponse à des signaux de commande détectés dans l'émission d'information de radiodiffusion ou de diffusion par câble.
9. Procédé selon la revendication 8, comprenant en outre l'étape d'interruption (395 et 39H de la figure 3A) du contrôleur pour forcer ledit micro-ordinateur à communiquer une donnée spécifique qui au récepteur à un instant spécifique.
10. Procédé selon la revendication 8, comprenant en outre l'étape consistant à donner instruction (205, 39J) au contrôleur de forcer ledit micro-ordinateur à communiquer une donnée spécifique au récepteur spécifique audi dispositif de sortie.
10. Procédé selon la revendication 8, comprenant en outre l'étape consistant à donner instruction (205, 39J) au contrôleur de forcer ledit micro-ordinateur à communiquer une donnée spécifique au récepteur spécifique audi dispositif de sortie.
11. Procédé selon la revendication 8, dans lequel ledit contrôleur peut communiquer un signal d'interruption à une pluralité de dispositifs de processeur et/ou de contrôleur, ledit procédé comprenant en outre l'étape de programmez dudit contrôleur afin d'intérompre l'un spécifique de ladite pluralité de dispositifs de processeur et/ou de contrôleur.
12. Procédé selon l'une quelconque des revendications 8 à 11, comprenant en outre les étapes de détection d'un signal d'interruption dans l'émission d'information et de commande dudit contrôleur pour communiquer ledit signal d'interruption détecté à un processeur ou contrôleur.
13. Procédé selon l'une quelconque des revendications 8 à 12, dans lequel, en réponse à la détection dudit signal de commande spécifique dans l'émission d'information, le micro-ordinateur est organisé pour gérer ladite donnée spécifique au récepteur en tant que partie d'une série de données spécifiques au récepteur, et un signal d'interruption de processeur est envoyé sur le micro-ordinateur pour permettre la communication d'une ou de plusieurs données spécifiques au récepteur spécifique audi dispositif de sortie à un instant spécifique.
14. Procédé selon la revendication 13, dans lequel ledit signal d'interruption est envoyé sur ledit micro-ordinateur en réponse à un second signal de commande supplémentaire détecté dans ladite émission d'information de radiodiffusion ou de diffusion par câble, et ledit signal d'interruption force ledit micro-ordinateur à renvoyer à l'écran d'affichage une image spécifique et à placer une donnée spécifique au récepteur générée au niveau de l'emplacement de mémoire spécifique afin de former une sorte combinée suivante.
15. Procédé selon la revendication 14, dans lequel un signal de commande détecté dans ladite omission d'information de radiodiffusion ou de diffusion par câble force ledit micro-ordinateur à cesser de communiquer une ou plusieurs données spécifiques au récepteur audi dispositif de sortie et à commencer ou à reprendre la génération de ladite sorte.
16. Procédé selon l'une quelconque des revendications 8 à 12, comprenant en outre les étapes de détection d'un programme de commande dans l'émission d'information et de centraiser dudit contrôleur à commander un ou plusieurs dispositifs de station de réception conformément audi programme de commande.
17. Procédé selon l'une quelconque des revendications précédentes, dans lequel ladite donnée spécifique au récepteur n'est pas communiquée automatiquement audi dispositif de sortie (202M), lorsque ladite donnée spécifique au récepteur est placée au niveau dudit emplacement de mémoire, et le procédé comprend en outre les étapes de détection (203), dans ladite émission d'information, d'un troisième signal de commande supplémentaire qui sera à donner instruction au micro-ordinateur (205) de communiquer la donnée spécifique au récepteur au niveau dudit emplacement de mémoire audi dispositif de sortie pour ainsi faire le micro-ordinateur (205) à communiquer ladite donnée spécifique au récepteur au dispositif de sortie (202M).
18. Procédé selon la revendication 13, comprenant en outre les étapes de détermination (39J) du fait que ledit micro-ordinateur n'a pas préparé à communiquer une première donnée spécifique au récepteur audi dispositif de sortie à un instant spécifique et par conséquent de contraindre (35J) dudit micro-ordinateur à exécuter une instruction de programme d'ordinateur spécifique pour ainsi commander la génération d'une donnée spécifique au récepteur suivante de ladite sorte.
19. Procédé selon l'une quelconque des revendications précédentes, dans lequel l'information qui est stockée dans ledit micro-ordinateur comprend des données spécifiques utilisées et le procédé comprend en outre l'étape de passage (203) de données de mise à jour au micro-ordinateur (205) de manière à provoquer la mise à jour

des données utilisateurs stockées de manière à ce que, lors de la génération d'une donnée spécifique au récepteur suivante, les données utilisateurs mises à jour soient traitées par ledit micro-ordinateur.

20. Procédé selon la revendication 19, dans lequel les données mises à jour sont détectées dans l'émission d'information de radiodiffusion ou de diffusion par câble et sont passées par un décodeur (20).

21. Procédé selon la revendication 19, dans lequel les données mises à jour sont reçues dans une émission d'information qui comprend une émission téléphonique.

22. Procédé selon la revendication 21, dans lequel ladite station de récepteur initie automatiquement ladite émission téléphonique pour une ou plusieurs données de mise à jour.

23. Procédé selon l'une quelconque des revendications précédentes, comprenant en outre les étapes de stockage (200) d'une information au niveau de la station de récepteur qui spécifie que ladite station de récepteur doit recevoir sélectionnement automatiquement une émission d'information spécifique, et de réception sélective (200) de ladite émission d'information conformément à ladite information stockée.

24. Procédé selon la revendication 23, dans lequel, en réponse à un signal de commande de validation, la station de récepteur est validée pour recevoir ledit programme de radiodiffusion ou de diffusion par câble en entrant (200) sur un processeur une ou plusieurs instructions du programme d'ordinateur permettant de commander (200) ladite station de récepteur afin de recevoir ladite émission d'information de radiodiffusion ou de diffusion par câble, de sélectionner ledit programme et de détecter ledits signaux de commande.

25. Procédé selon la revendication 23 ou 24, comprenant en outre les étapes de réception (200, figure 2) et de stockage (200, figure 2) d'une information d'émission préalable stocké programme spécifique.

26. Procédé selon l'une quelconque des revendications précédentes, comprenant en outre les étapes d'assemblage d'enregistrement (200, figure 2) au niveau de la station de récepteur qui réparent la disponibilité de séction et/ou utilisation de programmes de radiodiffusion ou de diffusion par câble, de signaux de commande sync de données utilisateur, et de communication (200, figure 2) de deux enregistrements à une station de collecte de données à distance.

27. Procédé selon l'une quelconque des revendications précédentes, comprenant en outre l'étape d'entrée (225) sur un processeur au niveau de la station de récepteur d'une information concernant la fonction d'un utilisateur à une sortie au niveau du dispositif de sortie (20M).

28. Procédé selon la revendication 27, comprenant en outre l'étape de treillage (200, figure 2, ou 205) de ladite information de fonction d'utilisateur en réponse à un quatrième signal de commande supplémentaire détecté dans l'émission d'information de radiodiffusion ou de diffusion par câble pour ainsi générer une information de réponse supplémentaire en plus de ladite information d'entrée.

29. Procédé selon la revendication 27 ou 28, comprenant en outre l'étape de communication (200, figure 2) de moins une certaine partie de ladite information d'entrée ou de ladite information de réponse supplémentaire à une station de collecte de données à distance.

30. Procédé selon l'une quelconque des revendications précédentes, dans lequel le programme de radiodiffusion ou de diffusion par câble et au moins certains des signaux de commandes contenus dans l'émission d'information sont cryptés et sont désignés par un signal indiquant une émission cryptée, et le procédé comprend en outre l'étape de commande (200, figure 2) d'un décrypteur dans la station de récepteur afin de décrypter ledit programme et des signaux de commande cryptés en réponse à la détection dudit signal désigné.

31. Procédé selon l'une quelconque des revendications précédentes, comprenant en outre l'étape de stockage de ladite émission d'information reçue sur un moyen de stockage (217, 255 ou 256) afin de permettre la délivrance de la sortie combinée à un instant où ledit programme de radiodiffusion ou de diffusion par câble n'est pas en train d'être reçu par la station de récepteur.

32. Procédé selon l'une quelconque des revendications précédentes, dans lequel le dispositif de sortie est un ou plusieurs dispositifs pris parmi le groupe constitué par une imprimante (221) pour émettre en sortie une information imprimée un générateur de son (263) pour émettre en sortie des sons, un dispositif d'affichage vidéo (202M) pour afficher une information vidéo, un dispositif de stockage vidéo (217) pour stocker une information vidéo, un dispositif de stockage audio (255) pour stocker une information audio et un émetteur intermédiaire (92).

imprimante un générateur de son (263) pour émettre en sortie des sons, un dispositif d'affichage vidéo (202M) pour afficher une information vidéo, un dispositif de stockage vidéo (217) pour stocker une information vidéo, un dispositif de stockage audio (255) pour stocker une information audio et un émetteur intermédiaire (92).

33. Procédé selon la revendication 32, dans lequel le dispositif de sortie est un moniteur TV (202M), ledit emplacement de mémoire spécifique est une RAM vidéo et ladite donnée spécifique au récepteur est mise à zéro audit emplacement de mémoire en placant une information d'une couleur qui change au niveau dudit emplacement de mémoire et ladite couleur qui change après la mise à jour de l'écran transparente lorsqu'elle est affichée au niveau dudit moniteur en combinaison avec une image de télévision.

34. Procédé selon la revendication 33, dans lequel remplacez de mémoire spécifique du micro-ordinateur, au niveau duquel la donnée spécifique au récepteur est placée est choisi sur la base de la détermination d'un point de référence et d'une dimension scalaire pour la donnée spécifique au récepteur lors de l'étape de génération (205) de ladite donnée spécifique au récepteur.

35. Procédé selon l'une quelconque des revendications précédentes, dans lequel ladite station de récepteur est une d'une pluralité de stations de récepteur similaires recevant le même émissien d'information, la donnée spécifique au récepteur générée au niveau de chaque station étant spécifique à sa station de récepteur, et la série de données (205) de ladite donnée spécifique au récepteur.

36. Procédé selon la revendication 35, dans lequel une période temporelle séparant la réception des stations de récepteur du signal de commande spécifique et la déception des stations de récepteur du troisième signal de commande supplémentaire suffit pour permettre à chaque micro-ordinateur du station de récepteur de terminer ladite étape de génération avant que chaque micro-ordinateur de station de récepteur reçoive ledit premier signal de commande supplémentaire.

37. Appareil de station de récepteur pour traiter des signaux afin de délivrer une sortie combinée constituée par un programme de radiodiffusion ou de diffusion par câble et par une donnée générée par ordinateur spécifique au récepteur, ladite station comportant un dispositif de sortie (20M) pour délivrer le programme de radiodiffusion ou de diffusion par câble et une autre information, ledit appareil comprenant:

- (1) recevoir une émission d'information comprenant un programme de radiodiffusion ou de diffusion par câble et un ou plusieurs signaux de commande;
- (2) détecter la présence des signaux de commande dans l'émission d'information;
- (3) passer les signaux de commande détectés à un micro-ordinateur (205);

ledit micro-ordinateur (205) étant connecté en fonctionnement audit dispositif de sortie (20M) et audit décodeur (203), ledit micro-ordinateur (205) comportant un emplacement de mémoire spécifique (PC-Microkey) du micro-ordinateur (205) connecté audit dispositif de sortie (20M) pour communiquer des données stockées dans ladit emplacement de mémoire spécifique (PC-Microkey) du micro-ordinateur (205) audit dispositif de sortie (20M), et ladit micro-ordinateur (205) étant programmé pour réaliser les étapes qui suivent sur la base d'un ou de plusieurs signaux de commande spécifiques:

- (1) génération d'une donnée spécifique au récepteur en traitant une information qui est stockée dans ledit micro-ordinateur (205) en réponse à la déception d'un signal spécifique;
- (2) placement de ladite donnée spécifique au récepteur dans ledit emplacement de mémoire spécifique (PC-Microkey) du micro-ordinateur (205);
- (3) communication de ledit donnée spécifique au récepteur au niveau dudit emplacement de mémoire spécifique (PC-Microkey) du micro-ordinateur (205) pour ainsi délivrer une sortie combinée constituée par ledit programme de radiodiffusion ou de diffusion par câble et par ladite donnée spécifique au récepteur au niveau dudit dispositif de sortie (20M) pendant la période temporelle entre ladite étape de placement de ladite donnée audit emplacement de mémoire (PC-Microkey) du micro-ordinateur (205) et ladite étape de remise à zéro de ladite donnée audit emplacement de mémoire (PC-Microkey) du micro-ordinateur (205);

38. Appareil selon la revendication 37, dans lequel ledit dispositif de sortie est un dispositif de sortie vidéo (202M) et

ledit signal de commande défectueux est un signal qui commande ledit micro-ordinateur (205) afin de placer une donnée vidéo spécifique au récepteur au niveau dudit aménagement spéciifique, ledit appareil comprenant en outre une mémoire de sortie vidéo (PC-Microkey de 205) connecté audit micro-ordinateur (205) et audit dispositif de sortie vidéo (202M) pour communiquer une information vidéo audit dispositif de sortie vidéo (202M),

6 39. Appareil selon la revendication 37 ou 38, dans lequel ledit dispositif de sortie est un dispositif de sortie audio (263) et ledit signal de commande défectueux est un signal qui commande ledit micro-ordinateur (205) pour placer une donnée audio spécifique au récepteur au niveau dudit aménagement spéciifique, ledit appareil comprenant en outre une mémoire de sortie audio (RAM audio de 205) connecté audit micro-ordinateur (205) et audit dispositif de sortie audio (263), pour communiquer une information audio audit dispositif de sortie audio (263).

40. Appareil selon l'une quelconque des revendications 37 à 39, comprenant en outre un contrôleur programmable (39 du décodeur 203) connecté audit micro-ordinateur (205) pour commander le traitement, la gérance et/ou l'émission en sortie dudit micro-ordinateur (205) en réponse à des signaux de commande défectueux dans une émission d'information de radiodiffusion ou de diffusion par câble.

41. Appareil selon la revendication 40, dans lequel ledit contrôleur (39 sur la figure 2A, 44 sur la figure 2B, 47 sur la figure 2C) est connecté en fonctionnement audit décodeur (203), ledit appareil comprenant en outre un processeur de commande de programme d'information (39) sur la figure 3A) pour commander la communication d'une information défectueuse dans ladite émission d'information.

42. Appareil selon la revendication 41, dans lequel ledit processeur de commande (39) entre un programme d'ordinateur sur un processeur sélectif (38), CPU de 205) ou sur un contrôleur (39, 20 de 200) ou force un processeur sélectif (39), CPU de 205) ou sur un contrôleur (39, 20 de 200) à modifier une matrice à identifier ou de répondre à un signal de commande dans ladite émission d'information, ledit appareil comprenant en outre un dispositif d'émission sélective (13 sur la figure 2D, 39 sur la figure 3A, 259 sur la figure 7) pour communiquer une information défectueuse dans ladite émission d'information audit processeur sélectif (38), CPU de 205) ou audit contrôleur sélectif (39, 20 de 200).

43. Appareil selon la revendication 42, dans lequel ledit dispositif d'émission sélective (13 sur la figure 2D, 39 sur la figure 3A, 259 sur la figure 7) est un bus (13 sur la figure 2D), un commutateur matriciel (39) ou un commutateur numérique (39).

44. Appareil selon l'une quelconque des revendications 41 à 43, dans lequel un dispositif quelconque pris parmi ledit contrôleur (39), ledit processeur de commande (39A) et ledit micro-ordinateur (205) comprend une pluralité de processeurs (39B, 39D, 39J) sur une unique microcircuit (39, figure 3A).

45. Appareil selon l'une quelconque des revendications 37 à 44, dans lequel le micro-ordinateur (205) reçoit une entrée comprenant un programme d'ordinateur et un ou plusieurs signaux d'interruption à geste ledit donnée spécifique au récepteur conformément audit programme d'ordinateur et un ou plusieurs signaux d'interruption, ledit appareil comprenant en outre un ou plusieurs tampons (8, 39A, 39C, 39E, 39G dans 205) ou mémoires (en 39B, en 39D, en 39J, 217, 217A) pour stocker et communiquer ledit programme d'ordinateur audit micro-ordinateur (205).

46. Appareil selon l'une quelconque des revendications 37 à 45, dans lequel un processeur (39J, 200) communique une instruction de commande basée sur un enregistrement de la présence ou de l'absence d'un programme ou d'une donnée spécifique au récepteur ledit appareil comprenant en outre une mémoire (mémoire de registre de première priorité) SPAM ou de seconde priorité SPAM en 39J; en 20, 14 ou 16 dans 200) pour stocker un ou plusieurs enregistrements de la présence ou de l'absence d'un programme ou d'une donnée spécifique au récepteur.

47. Appareil selon la revendication 45, lorsqu'elle dépend de la revendication 40, ou selon la revendication 46, dans lequel le contrôleur (39 du décodeur 203) envoie un signal d'interruption sur ledit micro-ordinateur (205) afin de forcer ledit micro-ordinateur (205) à communiquer une donnée spécifique au récepteur à un instant spécifique.

48. Appareil selon l'une quelconque des revendications 37 à 47, dans lequel une donnée spécifique au récepteur est émise en sortie en réponse à une réaction utilisatrice à une sortie au niveau dudit dispositif de sortie (202M),

ledit appareil comprenant en outre un dispositif d'enregistrement (225) pour entrer une information d'une réaction d'un utilisateur à une sortie, et un processeur (200, CPU de 205) connecté en fonctionnement audit dispositif d'enregistrement (225) pour traiter l'information entrée d'une réaction d'un utilisateur.

5 49. Appareil selon l'une quelconque des revendications 37 à 48, dans lequel ledit station émet en sortie sur une station à distance un enregistrement qui rapporte la disponibilité, l'utilisation et/ou l'usage d'un programme, d'un signal de commande ou d'une sorte combinée ou au niveau dudit récepteur ou d'une conteneur entrée de la réception d'un utilisateur à une sortie combinée constitutive par un programme de radiodiffusion ou de diffusion par câble reçus et par une donnée spécifique au récepteur au niveau dudit dispositif de sortie (202M), ledit appareil comprenant en outre un dispositif d'émission (connexion téléphonique 222 pour communiquer une entrée à une station à distance).

50. Appareil selon l'une quelconque des revendications 37 à 49, dans lequel ledit signal de commande spécifique à force ledit micro-ordinateur (205) à accéder à et à retrouver des données stockées au niveau d'un périphérique d'ordinateur (A; unité de disque de l'ordinateur 205), ledit appareil comprenant en outre une unité de mémoire périphérique d'ordinateur (232, 256) connectée audit micro-ordinateur (205) pour stocker lesdites données à retrouver.

51. Appareil selon l'une quelconque des revendications 37 à 50, comprenant en outre une mémoire (en 20 de 200) connectée à un récepteur (mélangeur 3 de la figure 2) pour stocker une information d'un programme sélectivement et pour recevoir depuis une station à distance une information d'un horaire ou d'une fréquence de l'émission dudit programme et un contrôleur (20) connecté à ladite mémoire (en 20) et à un tuner (214) pour forcer ladite station à recevoir ledit programme sélectivement audit horaire ou selon ladite fréquence.

52. Appareil selon l'une quelconque des revendications 37 à 51, comprenant en outre un dispositif de stockage (217, 225) connecté à un récepteur (201, 215) et à un dispositif de sortie (202M) pour recevoir et stocker, de manière à ce qu'au moins une quelconque information constituée par un programme reçu et par un signal de commande ledit ou par une donnée spécifique au récepteur soit stockée pour une émission en sortie d'ordre temporellement sur un utilisateur.

53. Appareil selon l'une quelconque des revendications 37 à 52, comprenant en outre un décodeur ou le débrayage de l'information d'un programme sélectif (217, 217A) à un dispositif de stockage (217, 217A) pour communiquer le programme provenant d'un décodeur (201, 215) ou à un dispositif de sortie (202M).

54. Appareil selon l'une quelconque des revendications 37 à 53, dans lequel ledit émission d'information est une émission multicanal, ledit appareil comprenant en outre un convertisseur (201) pour recevoir et convertir une certaine partie de ladite émission multicanal et pour convertir une certaine partie de ladite émission multicanal selon une fréquence de sortie spécifique.

55. Appareil selon l'une quelconque des revendications 37 à 54, dans lequel ledit émission d'information est une émission multicanal, ledit appareil comprenant en outre un convertisseur (201) pour recevoir et convertir une certaine partie de ladite émission multicanal et pour convertir une certaine partie de ladite émission multicanal selon une fréquence de sortie spécifique.

56. Appareil selon l'une quelconque des revendications 37 à 55, comprenant en outre une imprimante (221) et un emplacement de mémoire de la série d'impression (tampon d'impression de 205) en connexion avec ledit micro-ordinateur (205) et ladite imprimante (221) pour communiquer une information d'impression à ladite imprimante (221).

57. Appareil selon l'une quelconque des revendications 37 à 56, dans lequel ledit programme est un programme de télévision, ledit appareil comprenant en outre un tuner de télévision (215) pour recevoir un signal de télévision contenant ledit programme et un moniteur de télévision pour émettre en sortie ledit programme de télévision et ladite donnée spécifique au récepteur.

58. Appareil selon la revendication 37 et selon l'une quelconque des revendications 39 à 56, dans lequel ledit programme est un programme radio, ledit appareil comprenant en outre un tuner radio (209) pour recevoir un programme radio et un système de haut-parleur (253) pour émettre en sortie ledit programme et ladite donnée spécifique au récepteur.

69. Procédé de communication d'un produit du programme de mass media à une pluralité de stations de récepteur dont chacune inclut un décodeur de programme de radiodiffusion ou de diffusion par câble (unité 21/5), un dispositif de sortie (20/2M), un détecteur de signal de commande (décodeur 203), un micro-ordinateur (205) muni d'un emplacement de mémoire spécifique (PC-Microkey) ou micro-ordinateur 205) permettant de communiquer avec l'ensemble de sortie (202M), chaque station de récepteur étant adaptée pour détecter la présence d'un ou de plusieurs signaux de commande, pour générer une donnée spécifique au récepteur en réponse à un signal de commande spécifique détecté et pour délivrer au niveau dudit dispositif de sortie une sorte combinée constituée par le programme de radiodiffusion ou de diffusion par câble et par la donnée spécifique au récepteur, ledit procédé de communication comprenant les étapes de:
- 10 (1) réception d'un programme à émettre et délivrance du programme à un émetteur,
 (2) réception et stockage d'un signal de commande qui, au niveau de la station de récepteur, opère pour générer la donnée spécifique au récepteur; et
 (3) action consistant à provoquer la communication du signal de commande stocké sur un émetteur à un instant spécifique pour ainsi émettre une transmission d'information comprenant le programme et un ou plusieurs signaux de commande.
50. Procédé selon la revendication 59, dans lequel ladite émission d'information est émise sur deux de ladite pluralité de stations de récepteur en même temps et chaque des deux stations de récepteur délivre sa sorte combinée constituée par ledit programme de radiodiffusion ou de diffusion par câble reçu et par sa donnée spécifique au récepteur générée au niveau de son dispositif de sortie (202M) dans la même période temporelle.
51. Procédé selon la revendication 59, dans lequel ladite émission d'information est émise sur deux de ladite pluralité de stations de récepteur à différentes instants et chacune des deux stations de récepteur délivre sa sorte combinée constituée par ledit programme de radiodiffusion ou de diffusion par câble reçu et par sa donnée spécifique au récepteur générée au niveau de son dispositif de sortie (202K) dans une période temporelle différente.
52. Procédé selon l'une quelconque des revendications 59 à 61, dans lequel un emplacement de mémoire est connecté en fonctionnement à un ordinateur pour recevoir et stocker une certaine quantité de signal de commande, ledit procédé comprenant en outre les étapes de détection d'un signal qui permet, au niveau de la station d'émetteur, de générer et d'envoyer ledit signal de génération d'émission sur l'ensemble du programme d'émission à générer une certaine information dudit signal de commande et de placer ladite information au niveau dudit emplacement de mémoire.
55. Procédé selon la revendication 62, comprenant en outre l'étape de programmation dudit ordinateur afin de répondre aux signaux de génération d'émission en traitant une information stockée dans ledit ordinateur.
64. Procédé selon la revendication 62 ou 63, dans lequel ledit ordinateur traite une information spécifique de "formule et élément de cette émission" en réponse aux signaux de génération d'émission, comprenant en outre les étapes d'enrôle de données de "formule et élément" sur ledit ordinateur.
- 40 65. Procédé selon l'une quelconque des revendications 62 à 64, comprenant en outre la génération d'une certaine partie de soutien un programme d'ordinateur, soit un module de données en réponse aux signaux de génération d'émission.
- 45 66. Procédé selon l'une quelconque des revendications 59 à 65, comprenant en outre les étapes consistant à forcer un emplacement de mémoire qui peut stocker et communiquer un programme d'ordinateur à communiquer un programme d'ordinateur à un émetteur afin d'envoyer ledit programme d'ordinateur au moins une station de récepteur à charger ledit programme d'ordinateur au niveau d'un processeur et pour ainsi forcer ledit processeur à générer une information de sortie sous la commande dudit programme d'ordinateur.
- 50 67. Procédé selon la revendication 66, comprenant en outre l'étape d'assamblage dudit programme d'ordinateur stocké si communiqué selon un message muni d'une pluralité de segments, et ledit programme d'ordinateur est placé dans une partie spécifique dudit message et ledit message inclut une information qui force au moins une station de récepteur à enrouler ledit programme d'ordinateur sur l'un sélectionné d'une pluralité de processseurs.
- 65 68. Procédé selon la revendication 66 ou 67, comprenant en outre les étapes consistant à forcer un emplacement de mémoire qui peut stocker et communiquer ledit signal d'instruction à un

- ordinateur afin de générer une partie dudit programme d'ordinateur au niveau dudit ordinateur en déposant à côté.
69. Procédé selon l'une quelconque des revendications 59 à 68, dans lequel ladite station d'émetteur émet un ou plusieurs éléments pris parmi un signal vidéo, un signal audio et un signal de données dudit ou des éléments plusieurs éléments compris en outre l'élément de stockage dudit ou des éléments plusieurs éléments reçus à distance, ledit procédé comprenant en outre l'étape de stockage dudit ou des éléments plusieurs éléments reçus pris parmi un signal vidéo, un signal audio et un signal de données pendant une certaine période temporelle et ainsi, une émission dudit ou des éléments plusieurs éléments reçus pris parmi un signal vidéo, un signal audio et un signal de données est retardée.
- 10 70. Procédé selon l'une quelconque des revendications 59 à 69, dans lequel un contrôleur commande le passage d'un signal reçu spécifique, ledit procédé comprenant en outre les étapes de détection d'une information novée dans ledit signal reçu spécifique et de commande du passage dudit signal reçu spécifique sur la base de ladite information novée détectée.
- 15 71. Procédé selon la revendication 70, dans lequel ledit contrôleur commande un commutateur, ledit procédé comprenant en outre la commande dudit commutateur pour communiquer des signaux sélectivement depuis un ou plusieurs récepteurs d'entrée de programme et un ou plusieurs emplacements de mémoire à un ou plusieurs emplacements de mémoire et un ou plusieurs émetteurs.
- 20 72. Procédé selon la revendication 71, dans lequel ladite station d'émetteur émet une pluralité de messages sur l'une de ladite pluralité de stations de récepteur afin de commander ladite une station de récepteur pour délivrer sa sortie combinée constituée par ledit programme et par sa donnée spécifique au récepteur au niveau de son dispositif de sortie, ledit procédé comprenant en outre les étapes de communication d'un signal de communication d'un signal contenant un ou de ladite pluralité de messages provenant d'un récepteur d'entrée de programme à un emplacement de mémoire et de communication enroulant dudit signal contenant ledit un de facile pluralité de messages depuis ledit emplacement de mémoire à un émetteur.
- 25 73. Procédé selon l'une quelconque des revendications 70 à 72, dans lequel ladite station d'émetteur stocke au moins un programme, ledit procédé comprenant en outre les étapes de décodage dudit programme au niveau d'un récepteur d'entrée de radiodiffusion ou de diffusion par câble et de stockage et de stockage dudit programme au niveau dudit dispositif de stockage à l'aide d'un signal d'instruction qui permet, au niveau de la station d'émission, de commander un dispositif pris parmi ledit ordinateur et ledit contrôleur.
- 30 74. Procédé selon la revendication 73, comprenant en outre les étapes de décodage dudit signal d'instruction et de communication dudit signal d'instruction à un dispositif pris parmi ledit ordinateur et ledit contrôleur.
- 35 75. Procédé selon la revendication 71 et selon l'une quelconque des revendications 72 à 74 lorsque elle dépend de la revendication 71, comprenant en outre l'étape de commande dudit commutateur sur la base de la présence ou de l'absence d'un signal d'instruction stocké avec un programme.
- 40 76. Procédé selon l'une quelconque des revendications 59 à 75, dans lequel ladite station d'émetteur inclut une pluralité de récepteurs d'entrée de programme, ledit procédé comprenant en outre les étapes de traitement de signaux reçus au niveau de ladite pluralité de récepteurs d'entrée de programme, de communication d'une information de commande en réponse à une donnée noyée et de commande du passage d'un signal reçu au niveau de l'un des plusieurs de ladite pluralité de récepteurs d'entrée de programme sur la base de ladite information de commande communiquée.
- 45 77. Procédé selon l'une quelconque des revendications 59 à 76, dans lequel ledit ordinateur et ledit signal de génération de récepteur sont reçus depuis une ou plusieurs stations à distance, ledit procédé comprenant en outre les étapes de traitement d'un signal reçu depuis ladite une ou les autres plusieurs stations à distance ou de ladite commande de ladite station d'émission afin de communiquer ledit programme à un émetteur, et ledit signal de génération de récepteur audi ordinateur, sur la base d'une information dans ledit signal reçu traité.
- 50 78. Procédé selon l'une quelconque des revendications 59 à 77, comprenant en outre les étapes de réception dudit programme au niveau d'un récepteur dans la station d'émission, de communication dudit programme provoquant dudit récepteur à un emplacement de mémoire et de stockage dudit programme au niveau dudit emplacement de mémoire pendant une certaine période temporelle avant la communication dudit programme à un émetteur.

78. Procédé selon la revendication 78, comprenant en outre les étapes de réception du programme au niveau de l'un sélectionneur d'une pluralité de récepteurs dans la station d'émetteur et de communication du programme audit depuis ledit sélecteur sélectionné à un émetteur.
- 5 79. Procédé selon l'une quelconque des revendications 78 et 79, comprenant en outre les étapes d'émission dudit programme au niveau de l'un sélectionneur d'une pluralité d'émetteurs et de communication dudit programme audit émetteur sélectionné.
- 10 80. Procédé selon l'une quelconque des revendications 59 à 80, dans lequel un commutateur communique des signaux reçus sélectivement depuis au moins un récepteur et au moins un emplacement de mémoire à un émetteur, ledit procédé comprenant depuis au moins un signal qui permet, au niveau de la station d'émetteur, de donner en instruction une communication, et de commander dudit commutateur pour communiquer un signal reçu depuis un récepteur à un emplacement de mémoire en réponse audiu signal d'instruction.
- 15 82. Procédé selon la revendication 81 lorsqu'elle dépend de la revendication 62, dans lequel ledit signal reçu contient ledit signal de génération d'émetteur, ledit procédé comprenant en outre l'étape de communication ensuite d'au moins une certaine part du signal de génération d'émetteur depuis ledit emplacement de mémoire jusqu'à un second emplacement de mémoire.
- 20 83. Procédé selon la revendication 81, dans lequel ledit signal reçu contient ledit programme, ledit procédé comprenant en outre l'étape de commande dudit commutateur pour communiquer ledit programme à un émetteur.
- 25 84. Procédé selon l'une quelconque des revendications 59 à 83, dans lequel une pluralité de signaux sont reçus depuis une ou plusieurs stations à distance au niveau de l'actif station d'émetteur, ledit procédé comprenant en outre les étapes de sélection d'un ou de plusieurs de ladite pluralité de signaux et de communication de chaque signal sélectiommé à un dispositif de stockage.
- 29 85. Procédé selon la revendication 84 lorsqu'il s'agit de la revendication 70, dans lequel un ou plusieurs désœuds signaux sélectionnés est un signal qui permet, au niveau de la station d'émetteur, d'appliquer une instruction à un dispositif pris parmi ledit ordinateur et ledit contrôleur, ledit procédé comprenant en outre l'étape consistant à forcer un emplacement de mémoire à communiquer ledit signal d'instruction avec ledit instant spécifique et à commander ledit dispositif pris parmi ledit ordinateur et ledit contrôleur en réponse audiu signal d'instruction.
- 30 86. Procédé selon l'une quelconque des revendications 59 à 85, dans lequel une pluralité de signaux sont reçus depuis une ou plusieurs stations à distance et au moins l'un est stocké au niveau de ladite station d'émetteur et l'un de ladite pluralité de signaux octue opère pour réaliser une planification, ledit procédé comprenant en outre les étapes de programmation de ladite station d'émetteur afin de stocker la planification et de contenir dudit émetteur à émettre conformément à la planification.
- 35 87. Procédé selon la revendication 86, comprenant en outre l'étape consistant à forcer ladite station d'émetteur à générer conformément à la planification.
- 40 88. Procédé selon la revendication 86 ou 87, comprenant en outre l'étape consistant à accorder un récepteur ou à commander une station terrienne de satellite afin de recevoir un signal conformément à la planification.
- 45 89. Procédé selon l'une quelconque des revendications 59 à 88, comprenant en outre les étapes de réception d'une émission d'information depuis une station à distance, de détection dans l'émission d'information d'un signal d'instruction qui permet, au niveau de la station d'émetteur, d'exécuter un jeu d'instructions, de chargement d'un jeu d'instructions au niveau d'un ordinateur en réponse audiu signal d'instruction et sur la base dudit jeu d'instructions, de générer d'une information à traiter au niveau d'une station de récepteur ou de communication d'une information à associer audiu programme.
- 50 90. Procédé selon l'une quelconque des revendications 59 à 89, dans lequel un contrôleur commande un emplacement de mémoire afin de communiquer à un émetteur un signal de commande sélectionné, ledit procédé comprenant en outre les étapes de détection d'un signal qui permet, au niveau de la station d'émetteur, de donner en instruction une émission, et d'envoyer dudit signal sur ledit contrôleur pour ainsi forcer ledit emplacement de mémoire à communiquer un signal de commande sélectionné.

91. Procédé selon la revendication 90, comprenant en outre l'étape de programmation dudit contrôleur afin de répondre à un dci signal en commandant un emplacement de mémoire à sélectionner un signal de commande à communiquer un signal d'émision d'instruction en vu dans une émission d'information de radiodiffusion ou de diffusion par câble ou en forçant un emplacement de mémoire à communiquer un signal d'émision d'instruction en vu dans une émission d'information de radiodiffusion ou de diffusion par câble dimise par une station à distance.
- 5 92. Procédé selon la revendication 90 ou 91, dans lequel ledit signal d'émision d'instruction en vu dans une émission d'information de radiodiffusion ou de diffusion par câble dimise par une station à distance.
- 10 93. Procédé selon l'une quelconque des revendications 90 à 92, comprenant en outre les étapes de stockage d'un signal qui permet, au niveau de la station d'émetteur, d'appliquer une instruction, et de commander dudit emplacement de mémoire afin de communiquer un signal de commande sélectionné à un instant planifié conformément audiu signal d'instruction.
- 15 94. Procédé selon l'une quelconque des revendications 90 à 93, comprenant en outre l'étape de stockage dudit signal audiu emplacement de mémoire avec ledit programme.
- 16 95. Procédé selon l'une quelconque des revendications 90 à 94, comprenant en outre les étapes de commande d'un emplacement de mémoire afin de communiquer ledit programme à un émetteur en réponse à un primaire signal d'instruction et de commande d'un emplacement de mémoire afin de communiquer un signal de commande sélectionné en réponse à un second signal d'instruction.
- 20 96. Procédé selon la revendication 95, comprenant en outre les étapes de détection d'un signal de commande communiqué depuis ledit emplacement de mémoire et de programmation d'un contrôleur pour répondre à un signal de commande communiqué depuis ledit emplacement de mémoire.
- 25 97. Procédé selon l'une quelconque des revendications 90 à 96, comprenant en outre l'étape consistant à noyer un signal d'instruction dans ledit programme pour ainsi permettre à un contrôleur de répondre audiu signal d'instruction reçue à un instant ledit programme est en train d'être communiquée.
- 30 98. Procédé selon la revendication 64 et selon l'une quelconque des revendications 65 à 77 lorsqu'elle dépend de la revendication 64, dans lequel ledit signal de génération d'amateur ou leadies données de "formule et élément" sont reçues dans une émission d'information de radiodiffusion ou de diffusion par câble émise par la station à distance, ledit procédé comprenant en outre les étapes de déception d'un signal d'instruction provenant d'une station à distance et d'émission de ladite information "formule et élément" en réponse à cela.
- 35 99. Procédé selon l'une quelconque des revendications 59 à 98, comprenant en outre les étapes de stockage et d'émission sur une station de récepteur de données qui spécifient un canal d'émission ou un canal de transmission d'un quelconque produit considéré d'un programme spécifique et d'émission ensuite dudit programme conformément aux données spécifiées pour ainsi permettre à ladite station de récepteur de sélectionner et de stocker ou de sélectionner et d'émettre en sortie ledit programme.
- 40 100. Procédé selon l'une quelconque des revendications 59 à 99, comprenant en outre les étapes de stockage et d'émission sur une station de récepteur de données qui spécifient un canal d'émission ou un canal de transmission d'un quelconque produit considéré d'un programme spécifique et d'émission ensuite dudit programme conformément aux données spécifiées pour ainsi permettre à ladite station de récepteur de sélectionner et de stocker ou de sélectionner et d'émettre en sortie ledit programme.
- 45 101. Procédé selon l'une quelconque des revendications 59 à 100, comprenant en outre les étapes d'émission sur une station de récepteur d'un signal de commande pour forcer ladite station à émettre un signal de commande à un traitement parallèle et à sélectionner et à émettre sur un micro-ordinateur une quelconque information associée à un programme ou un signal de commande émis dans une émission d'information de radiodiffusion ou de diffusion par câble et pour forcer ledit micro-ordinateur à traiter une information stockée et à gérer une sortie en réponse à ladite information entrée.
- 50 102. Procédé selon la revendication 100 ou 101, comprenant en outre les étapes de communication à un générateur de signal de données qui spécifient un instant d'émission ou un canal d'émission d'un quelconque produit considéré d'un programme spécifique ou d'un signal de commande et d'émission de données communiquées ou dudit signal de commande à une partie spécifique d'une émission d'information de radiodiffusion ou de diffusion par câble ou d'émission directe données communiquées ou dudit signal de commande communiquée à une émission d'information de radiodiffusion ou de diffusion par câble dans un message d'un format spécifique.

103. Procédé selon l'une quelconque des revendications 59 à 102, comprenant en outre les étapes consistant à forcer un emplacement de mémoire qui permet de stocker et de communiquer un signal qui permet, au niveau de la station de récepteur, de réaliser une synchronisation, à communiquer ledit signal à un émetteur afin d'émettre ledit signal pour ainsi forcer l'au moins une station de récepteur à commencer l'exécution de fonctions commandées sélectionnées programmées ou nivée d'abord en réponse à une information sélectionnée dans l'information de radiodiffusion ou de diffusion par câble diffusé par ledit émetteur.

104. Procédé selon l'une quelconque des revendications 59 à 103, comprenant en outre les étapes consistant à forcer un emplacement de mémoire qui permet de stocker et de communiquer un signal qui permet, au niveau de la station de récepteur, de réaliser une interruption à communiquer ledit signal à un émetteur afin d'émettre ledit signal pour ainsi forcer l'au moins une station de récepteur à interrompre le traitement d'un micro-ordinateur, contreleur ou processeur sélectionné en réponse à ce dernier.

105. Procédé selon l'une quelconque des revendications 59 à 104, comprenant en outre les étapes consistant à forcer un emplacement de mémoire qui permet de stocker et de communiquer un signal qui peut, au niveau de la station de récepteur, jouer le rôle de source à partir duquel la station de récepteur est sélectionnée une donnée spécifique au récepteur à gérer, à communiquer le signal à un émetteur afin d'émettre ledit signal pour ainsi forcer l'au moins une station de récepteur à sélectionner une donnée spécifique au récepteur à générer.

106. Procédé selon la revendication 105, dans lequel ledit signal qui peut, au niveau de la station de récepteur, jouer le rôle de source est émis avant ledit signal de génération de récepteur et ainsi, faisons une station de récepteur stocke des données reçues dans ledit signal de source et gère une donnée spécifique au récepteur en traitant lesdites données stockées.

107. Procédé selon l'une quelconque des revendications 59 à 106, comprenant en outre les étapes consistant à forcer un emplacement de mémoire qui permet de stocker et de communiquer un signal qui permet, au niveau de la station de récepteur, de cesser une combinaison, à communiquer le signal à un émetteur afin d'émettre ledit signal pour ainsi forcer l'au moins une station de récepteur à cesser de combiner sa donnée spécifique au récepteur générée à un instant spécifique.

108. Procédé selon l'une quelconque des revendications 59 à 107, comprenant en outre les étapes consistant à forcer un emplacement de mémoire qui permet de stocker et de communiquer un signal qui, au niveau de la station de récepteur, opère pour réaliser une combinaison, à communiquer le signal à un émetteur afin d'émettre ledit signal pour ainsi forcer l'au moins une station de récepteur à délivrer une sortie combinée constituée par ledit programme de radiodiffusion ou de diffusion par câble reçu et par ladite donnée spécifique au récepteur au niveau de son dispositif de sortie à un instant spécifique.

109. Procédé selon l'une quelconque des revendications 59 à 108, comprenant en outre les étapes consistant à forcer un emplacement de mémoire qui permet de stocker et de communiquer un signal qui, au niveau de la station de récepteur, opère pour remettre à zéro une donnée spécifique au récepteur générée, à communiquer ledit signal à un émetteur afin d'émettre ledit signal pour ainsi forcer l'au moins une station de récepteur à remettre à zéro sa donnée spécifique au récepteur générée en réponse à celle-ci.

110. Procédé selon l'une quelconque de la station d'émission de donner en instruction une génération, dans un signal pris parmi un signal de télévision et un signal radio ou au niveau d'un emplacement de mémoire qui stocke soit un programme de télévision, soit un programme de radio.

111. Procédé selon l'une quelconque des revendications 59 à 110, dans lequel la station d'émission est une station d'émetteur intermédiaire à distance, le dispositif de sortie (202M) est un émetteur (83, 87, 91, 92), le micro-ordinateur (205) est une unité de commande automatique (73) pour la station d'émission et l'emplacement de mémoire spécifique est une mémoire de programme établi pour l'émission, ledit procédé comprenant en outre les étapes de:

(1) réception d'un ou de plusieurs signaux d'instruction qui permettent, au niveau d'une station d'émission, de donner instruction à un ordinateur (73, 205) ou à un processeur (en 71, 200, 35J) la manière de recevoir ou de présenter un produit de programme de télévision ou une série d'ordinateurs ou de fonctionner sur la base d'une réception de téléspectateurs à une présentation de télévision ou à une programmation de télévision ou à une présentation de télévision ou à une programmation de radiodiffusion ou de diffusion par câble et par une demande générée par un ordinateur spé-

nateur et de délivrer l'un ou les plusieurs signaux de commande qui, au niveau de la station d'émission intermédiaire (2) réception d'un ou de plusieurs signaux de commande qui, au niveau de la station d'émission intermédiaire à distance, opèrent pour exécuter ou commander ledit un ou lesdits plusieurs signaux d'instruction; et (3) contraints dudit un ou desdits plusieurs signaux de commande à être communiqués aussi directement avant ledit instant spécifique pour ainsi permettre une émission d'instruction comprenant l'un ou les plusieurs signaux d'instruction et l'un ou les plusieurs signaux de commande.

112. Procédé selon l'une quelconque des revendications 59 à 111, dans lequel la station de récepteur est une station d'émetteur intermédiaire à distance, le dispositif de sortie (202M) est un émetteur (83, 87, 91, 92), le micro-ordinateur (205) est une unité de commande automatique (73) pour la station d'émission intermédiaire et l'emplacement de mémoire spécifique est une mémoire (73) ou un enregistreur (76 ou 78), ledit procédé comprenant en outre l'une des étapes suivantes:

(1) réception dudit programme et délivrance dudit programme à un émetteur ayant ledit instant spécifique; (2) réception d'un ou de plusieurs signaux d'instruction qui permettent, au niveau d'une station d'abonnement, de donner instruction à un ordinateur (73, 205) ou à un processeur (en 71, 200, 35J) la manière de recevoir ou de présenter un produit associé aussi programme et de locataire sur la base d'une réaction d'utilisateur à une sonde bascule dudit programme et de délivrer l'un ou les plusieurs signaux d'instruction à un émetteur à distance, opérant pour sélectionner ou communiquer ledit programme et de planification à un émetteur à distance; (3) réception d'un ou de plusieurs signaux de commande qui, au niveau de la station d'émission intermédiaire à distance, opérant pour sélectionner ou communiquer ledit programme et de délivrer l'un ou les plusieurs signaux d'instruction et délivrance dudit un ou plusieurs signaux de commande à un émetteur ayant ledit instant spécifique; et (4) réception d'une planification qui, au niveau de la station d'émission intermédiaire à distance, opère pour émettre ledit programme si bascule un ou plusieurs signaux d'instruction et délivrance de la planification à un émetteur ayant ledit instant spécifique.

113. Procédé selon l'une quelconque des revendications 59 à 112, dans lequel une station d'émission recçoit depuis une station d'abonnement une quelconque information d'un abonné à une programmation de télévision ou à une présentation de sortie d'ordinateur, ledit procédé comprenant en outre au moins l'une des étapes suivantes:

émission sur une station d'abonnement d'un programme d'ordinateur qui traite une certaine information d'une réception d'un abonné à une programmation de télévision ou à une présentation de sortie d'ordinateur, affichage d'une certaine variété d'un signal d'instruction sur la base d'une réaction d'un abonné à une programmation de télévision ou à une présentation de sortie d'ordinateur; et émission d'une certaine partie d'un programme de télévision ou d'un signal d'instruction sur la base d'une réaction d'un abonné à une programmation de télévision ou à une présentation de sortie d'ordinateur.

114. Procédé selon l'une quelconque des revendications 59 à 113, comprenant en outre les étapes consistant à forcer une station d'abonnement à émettre ledit programme et à forcer une seconde station d'abonnement à émettre ledit signal de commande qui, au niveau de la station de récepteur, opère pour générer la donnée spécifique au récepteur ou à émettre un module de données qui, au niveau de la station de récepteur, opère pour générer la donnée spécifique au récepteur afin de réaliser une sélection et une génération.

115. Procédé selon l'une quelconque des revendications 59 à 114, dans lequel ledit programme est émis sur une station d'abonnement par satellite et une seconde station d'abonnement à radiodiffuser ou à diffuser par câble sur ladite station d'abonnement ledit signal de commande au locut module de données associé audi programme.

116. Procédé selon l'une quelconque des revendications 59 à 115, comprenant en outre l'émission d'une pluralité de programmes et d'un ou de plusieurs signaux qui permettent, au niveau d'une station d'abonné d'analyser une valeur ou de générer une justification pour ainsi forcer au moins une station d'abonné à déclencher l'un desdits plusieurs programmes sur la base de sa valeur potentielle pour un abonné ou à émettre en sortie deux ou plusieurs sélectifs programmés selon un ordre spécifique au récepteur.

117. Appareil de station d'émission pour traiter des signaux et communiquer des produits de programme de mass media afin de présenter au niveau de chaque d'une pluralité de stations de récepteur une sonde combinée constituée par un programme de radiodiffusion ou de diffusion par câble et par une demande générée par un ordinateur spé-

- clique au récepteur, chacune desdites stations de réception comportant un dispositif de sortie (202M) pour recevoir et délivrer le programme de radiodiffusion ou de diffusion par câble et toute autre information, ladite station comportant également un micro-ordinateur (205) munie d'un emplacement de mémoire spécifique (PC-MicroKey du micro-ordinateur 205) connecté en fonctionnement audit premier processeur de sortie (202M) pour stocker et émettre en toute une information sur ledit dispositif de sortie (202A), ledit appareil de station d'émetteur comprenant:
- 6 un émetteur de radiodiffusion ou de diffusion par câble (83, 87, 91 ou 92) pour communiquer à une pluralité de stations de réception une émission d'information comprenant un programme et un ou plusieurs signaux de commande;
- 10 un récepteur d'entrée de programme audit émetteur (83, 87, 91 ou 92);
- 14 ou 92) pour communiquer un signal qui permet, au niveau de la station d'émetteur (83, 87, 91 ou 92) pour stocker et communiquer un signal qui, au niveau de la station de récepteur, opère pour gérer la donnée spécifique au récepteur; et
- 15 un dispositif d'entrée (98, 74, 50-62) connecté en fonctionnement audit mémoire (73) ou audit enregistreur (76 ou 78) pour forcer ladite mémoire (73) ou audit enregistreur (76 ou 78) à communiquer l'ordre signal de commande à un instant spécifique audit émetteur (83, 87, 91 ou 92) afin d'alors communiquer ledit programme et ledit signal de commande auxdites stations de réception et ainsi forcer chacune de ladite pluralité de stations de réception à délivrer ledit programme au niveau de son dispositif de sortie (202M), à gérer (205) une donnée spécifique à la station de récepteur, à placer sa donnée spécifique à la station de récepteur au niveau de son emplacement de mémoire (PC-MicroKey du micro-ordinateur 205) pendant une période temporelle et à délivrer une sorte combinée constituée par ledit programme de radiodiffusion ou de diffusion par câble et par sa donnée spécifique de station de récepteur au niveau de son dispositif de sortie (202A),
- 20 11B. Appareil de station d'émetteur selon la revendication 117, dans lequel ladite station d'émetteur émet sur ladite pluralité de stations de récepteur une première donnée spécifique à l'émetteur et au moins l'une de ladite pluralité de stations de récepteur présente une certaine information d'une donnée spécifique au récepteur sur la base de ladite première donnée spécifique à l'émetteur; ledit appareil comprenant en outre:
- 24 une seconde mémoire (3) ou un second enregistreur (76 ou 78) connecté en fonctionnement audit émetteur (83, 87, 91 ou 92) pour stocker et communiquer une donnée spécifique à l'émetteur, qui, au niveau de la station de récepteur, joue le rôle de base pour calculer une certaine information d'une donnée spécifique au récepteur.
119. Appareil de station d'émetteur selon la revendication 117, dans lequel ladite station d'émetteur émet sur ladite pluralité de stations de récepteur une seconde donnée spécifique à l'émetteur et au moins l'une de ladite pluralité de stations de récepteur, dont une partie latente secondo domino spécifique à l'émetteur au niveau de son dispositif de sortie (202M), ledit appareil comprenant en outre:
- 35 une troisième mémoire (73) ou un troisième enregistreur (76 ou 78) connecté en fonctionnement audit émetteur (83, 87, 91 ou 92) pour stocker et communiquer certaines données qui, au niveau de la station de récepteur, jouent le rôle de source depuis lesquelles est élaborée une donnée spécifique au récepteur à gérer.
- 40 120. Appareil de station d'émetteur selon l'une quelconque des revendications 117 à 119, dans lequel ledit dispositif distinct entre un premier signal d'avancement qui permet ensuite, au niveau de la station d'émetteur, audit instant spécifique, d'émettre en sonde ladite mémoire (73) ou ledit enregistreur (76 ou 78) nommée en premier sur ledit émetteur (83, 87, 91 ou 92), ledit appareil comprenant en outre:
- 45 un premier processeur (73) connecté en fonctionnement audit dispositif d'entrée (50-62, 74, 98) pour distinguer un signal d'avancement;
- 50 un premier contrôleur de mémoire (73, 205C en 73) connecté en fonctionnement audit premier processeur (73) pour commander une mémoire (73) ou un enregistreur (76 ou 78) afin de stocker un ou plusieurs signaux d'avancement; et
- 55 une quatrième mémoire (73) ou un quatrième enregistreur (76 ou 78) connecté en fonctionnement audit premier contrôleur (73, 205C en 73) pour stocker ledit premier signal d'avancement.
121. Appareil de station d'émetteur selon l'une quelconque des revendications 117 à 120, dans lequel un certain dispositif d'entrée (98, 74, 50-62) entre un signal d'instruction qui permet, au niveau de la station d'émetteur, d'émettre un sonde ladite mémoire (73) ou ledit enregistreur (76 ou 78) nommée en premier sur ledit émetteur (83, 87, 91 ou 92) audit instant spécifique, ledit appareil comprenant en outre:

- 5 un premier processeur de commande (39J, 73) connecté en fonctionnement audit dispositif d'entrée (98, 74, 50-62) pour distinguer un signal qui permet, au niveau de la station d'émetteur, d'appliquer une instruction; et
- 10 un premier contrôleur de sortie (73, 205C en 73, 39) dans un quelconque décodateur; 12 dans 71) connecté en fonctionnement audit premier processeur de commande (73) pour émettre en sorte un signal de commande qui permet d'envoyer en sorte une mémoire (73) ou un enregistreur (76 ou 78);
122. Appareil de station d'émetteur selon l'une quelconque des revendications 117 à 121, comprenant en outre un dispositif pris parti:
- 14 un premier contrôleur de dispositif d'émission télévisée (73) connecté en fonctionnement audit récepteur d'en-tête de programme (76, 78, 53-62) pour commander un premier dispositif d'émission additive (75, 76, 78, 116) de programme (76, 78, 53-62) pour commander un premier dispositif d'émission additive (75, 76, 78, 53-62) pour communiquer un ou plusieurs signaux à une mémoire (73) ou à un enregistreur (76 ou 78) pour un instant spécifique;
- 18 un second contrôleur de dispositif d'émission additive (73) connecté en fonctionnement audit émetteur de radiodiffusion ou de diffusion par câble (83, 87, 91, 92) pour commander un second dispositif d'émission additive (75, 76, 78) afin de communiquer un ou plusieurs signaux depuis une ou plusieurs mémoires (73) et/ou enregistreurs (76 ou 78) à un instant spécifique.
123. Appareil de station d'émetteur selon l'une quelconque des revendications 117 à 122, comprenant en outre:
- 20 un contrôleur central (73) connecté en fonctionnement à un dispositif pris parti ledit récepteur d'en-tête de programme (76, 78, 53-62) et ledit émetteur de radiodiffusion ou de diffusion par câble (83, 87, 91, 92) pour commander la communication sur ladite une partie prise parmi une certaine partie dudit programme, une certaine partie d'un message à associer audit programme, une ou plusieurs données qui identifient ledit programme, une certaine information d'avancement dudit programme, une ou plusieurs données qui désignent le point de début d'une certaine partie dudit programme ou un signal qui désigne ledit programme et qui permet, au niveau de la station de récepteur, d'appliquer une instruction:
- 24 124. Appareil de station d'émetteur selon la revendication 123, comprenant en outre un dispositif pris parti:
- 26 une horloge connectée en fonctionnement audit contrôleur central (73); et
- 30 un second dispositif d'entrée (98, 74, 50-62) connecté en fonctionnement audit contrôleur central (73) pour enregistrer une ou plusieurs instructions de commande de cadencement.
- 35 125. Appareil de station d'émetteur selon la revendication 123 ou 124, comprenant en outre un dispositif pris parti:
- 39 un second processeur (73, dans 71, dans un quelconque décodeur) connecté en fonctionnement audit contrôleur central (73) pour distinguer un signal de commande de cadencement ou un instant auquel il convient de laisser passer un signal qui est permis d'appliquer une instruction;
- 43 un second contrôleur de mémoire (73) connecté en fonctionnement audit contrôleur central (73) pour commander une mémoire d'émission (76 ou 78) afin de stocker un signal d'avancement qui permet d'appliquer une instruction, et
- 47 une cinquième mémoire (73) ou un cinquième enregistreur (76 ou 78) connecté en fonctionnement audit contrôleur central (73) pour stocker deux signaux ou plus en ordre.
- 51 126. Appareil de station d'émetteur selon l'une quelconque de la revendication 119 et des revendications 120 à 125 lorsque celle-ci dépasse de la revendication 119, comprenant en outre:
- 55 un premier ordinateur (73) connecté en fonctionnement à un algorithme pris parti secondo mémoire (73) ou ledit ordinateur (73) connecté en fonctionnement à ladite troisième mémoire (73) ou ledit troisième enregistreur (76 ou 78) pour recevoir des données "formule et élément de cette émission" et pour émettre en sorte une certaine partie d'un module de données sur cette mémoire (73) au cas enregistreur (76 ou 78).
- 59 127. Appareil de station d'émetteur selon l'une quelconque des revendications 117 à 126, dans lequel un certain dispositif signal pris parti commande une information "formule et élément de cette émission", ledit appareil comprenant en outre:
- 63 un second ordinateur (73) connecté en fonctionnement à ladite mémoire (73) ou audit troisième enregistreur (76 ou 78) nommé en premier pour émettre en sorte une information "formule et élément de cette émission" en réponse à un signal d'instruction qui permet, au niveau de la station d'émetteur, de réaliser une gondolation.

128. Appareil de station d'émetteur selon l'une quelconque de la revendication 120 et des revendications 121 à 127 lorsqu'elle dépend de la revendication 120, dans lequel un signal contenant un code d'ordre programme entre un signal d'avant-courant codé qui permet, au niveau de la station d'émetteur, d'émettre en sortie audio mémoire (73) ou lecteur enregistreur (76 ou 78) nommé en premier sur ledit émetteur (83, 87, 91 ou 92), ledit appareil comprenant en outre:
- 6 un premier décodeur (71, 77, 79) connecté en fonctionnement auditif dispositif d'entrée (98, 74, 50-52) pour décoder une information codée dans un signal contenant un programme;
- 10 un troisième dispositif d'émission sélective (en 39, en 11) connecté en fonctionnement auditif premier décodeur (en 71) pour communiquer auditif premier processeur (en 39, en 71) une ou plusieurs données.
14. Appareil de station d'émetteur tel que dépend de la revendication 122, dans lequel ledit décodeur (en 71, 77, 79) décode une ou plusieurs données qui permettent, au niveau de la station d'émetteur, de relâcher une communication sur la station de récepteur d'une certaine partie du signal contenant ledit programme, ledit appareil comprenant en outre:
- 15 un quatrième dispositif d'émission sélective (en 39, en 11) connecté en fonctionnement auditif premier décodeur (en 71) pour communiquer auditif premier processeur de commando (en 39, en 11) une ou plusieurs données; et un cinquième dispositif d'émission sélective (en 39, en 71) connecté en fonctionnement auditif premier processeur de commande (en 39, en 71) pour communiquer auditif premier contrôleur de dispositif d'émission sélective (73) un signal qui permet d'appliquer une instruction.
130. Appareil de station d'émetteur selon l'une quelconque des revendications 117 à 129, dans lequel ledit dispositif d'émission (98, 74, 50-52) inclut un premier récepteur (50-52, 71, 73) pour recevoir depuis une station à distance un signal qui permet, au niveau de la station d'émetteur, d'appliquer une instruction.
- 25 131. Appareil de station d'émetteur selon l'une quelconque des revendications 117 à 130, dans lequel ledit premier ordinateur (73) ou lecteur second ordinateur (73) gère une certaine sortie en réponse à un signal d'instruction qui permet, au niveau de la station d'émetteur, de réaliser une génération; ledit appareil comprenant en outre:
- 30 une sixième mémoire (73) ou un sixième enregistreur (76 ou 78) pour stocker un signal d'instruction qui permet, au niveau de la station d'émetteur, de réaliser une génération; et un troisième dispositif d'entrée (76, 55-52) connecté en fonctionnement à ledit système mémoire (73) ou lecteur sixième enregistreur (76 ou 78) pour recevoir depuis un autre appareil un signal d'instruction qui permet, au niveau de la station d'émetteur (76 ou 78) pour forcer ledit lecteur à arrêter un sixième dispositif d'émission sélective (73) connocit en fonctionnement auditif sixième enregistreur (76 ou 78) pour recevoir et transférer un ou plusieurs signaux d'instruction.
- 35 40 132. Appareil de station d'émetteur selon la revendication 131 comprenant en outre:
- un troisième processeur (73) connecté en fonctionnement auditif second dispositif d'entrée (73, 98, en 71) et auxit second contrôleur de mémoire (73) pour distinguer un signal d'instruction qui permet, au niveau de la station d'émetteur, de réaliser une génération et pour faire ledit second contrôleur de mémoire (73) à commander ledite sixième mémoire (73) ou lecteur sixième enregistreur (76 ou 78) afin de stocker ledit signal d'instruction distingué.
- 45 133. Appareil de station d'émetteur selon la revendication 131 ou 132, dans lequel ledit second dispositif d'entrée (73, 74, 98, en 71) effect, depuis une seconde station à distance, ledit signal d'instruction qui permet, au niveau de la station d'émetteur, de réaliser une génération.
- 50 134. Appareil de station d'émetteur selon l'une quelconque des revendications 131 à 133, comprenant en outre:
- un contrôleur SPAN 205C en 73, 39 dans un quelconque décodeur, 12 en 71) connecté en fonctionnement à un ordinateur spécifique (73) pour commander ledit ordinateur spécifique (73) afin de générer ou d'arrêter en sortie un programme d'ordinateur ou un module de données conformément à un signal d'instruction qui permet, au niveau de la station d'émetteur, de réaliser une génération.
- 55 135. Appareil de station d'émetteur selon l'une quelconque des revendications 128 à 134, dans lequel ledit récepteur d'entrée de programme (76, 58, 53-62) entre un signal d'instruction codé qui est reçu avec ledit programme et qui permet, au niveau de la station d'émetteur, de réaliser une génération, ledit appareil comprenant en outre:

- un septième dispositif d'émission sélective (en 71, en 77, 79) connecté en fonctionnement auditif premier décodeur (en 71, 77, 79) pour recevoir et transcrire un signal identifié à un quantième processeur (73) ou lecteur enregistreur (76 ou 78) nommé en premier sur ledit émetteur (83, 87, 91 ou 92), ledit appareil comprenant en outre:
- 6 un signal qui permet, au niveau de la station d'émetteur, d'appliquer une instruction.
- 10 136. Appareil de station d'émetteur selon l'une quelconque des revendications 117 à 135, dans lequel ledit station d'émetteur émet un ou plusieurs signaux qui permettent, au niveau de la station de récepteur, de donner instruction à l'emplacement de mémoire spécifique de combiner ou de cesser de combiner ou de remettre à zéro une donnée générée par un ordinateur spécifique au récepteur, ledit appareil comprenant en outre:
- un quatrième dispositif d'entrée (50-52, 74, 98) connecté en fonctionnement à un émetteur de radiodiffusion ou de diffusion par câble (83, 87, 91 ou 92) pour communiquer audit émetteur de radiodiffusion ou de diffusion par câble (83, 87, 91 ou 92) à un troisième instant spécifique un ou plusieurs signaux qui permettent, au niveau de la station de récepteur, d'appliquer une instruction.
- 15 137. Appareil de station d'émetteur selon la revendication 136, dans lequel une troisième station à distance communiquant un ou plusieurs signaux qui permettent, au niveau de la station de récepteur, d'appliquer une instruction, ledit appareil comprenant en outre:
- une instruction, ledit appareil comprenant en outre:
- un second récepteur (50-52, 71, 73) connecté en fonctionnement à un dispositif d'amission sélective (73, 75, en 71, 39 dans un quelconque décodeur pour stocker un ou plusieurs signaux qui permettent, au niveau de la station de récepteur, d'appliquer une instruction; et un cinquième dispositif d'entrée (50-52, 74, 98) connecté en fonctionnement à ledit septième mémoire (73) ou lecteur septième enregistreur (76 ou 78) pour stocker ledit septième mémoire (73) ou lecteur septième enregistreur (76 ou 78) à arrêter en, suite sur un émetteur de radiodiffusion ou de diffusion par câble (83, 87, 91 ou 92) à un instant spécifique un ou plusieurs signaux qui permettent, au niveau de la station de récepteur, d'appliquer une instruction.
- 20 138. Appareil de station d'émetteur selon la revendication 136 ou 137, comprenant en outre:
- une septième mémoire (73) ou un septième enregistreur (76 ou 78) connecté en fonctionnement à un dispositif d'émission sélective (73, 75, en 71, 39 dans un quelconque décodeur pour stocker un ou plusieurs signaux qui permettent, au niveau de la station de récepteur, d'appliquer une instruction; et un second récepteur (50-52, 71, 73) connecté en fonctionnement à ledit septième mémoire (73) ou lecteur septième enregistreur (76 ou 78) pour stocker ledit septième mémoire (73) ou lecteur septième enregistreur (76 ou 78) à arrêter en, suite sur un émetteur de radiodiffusion ou de diffusion par câble (83, 87, 91 ou 92) à un instant spécifique un ou plusieurs signaux qui permettent, au niveau de la station de récepteur, d'appliquer une instruction.
- 25 139. Appareil de station d'émetteur selon l'une quelconque des revendications 117 à 138, dans lequel ledit récepteur d'entrée de programme (76, 58, 53-62) est une huitième (73) ou un enregistreur (76 ou 78) au niveau duquel au moins une certaine part dudit programme est stockée, ledit appareil comprenant en outre:
- un deuxième dispositif d'entrée (50-52, 74, 98) connecté en fonctionnement auditif récepteur d'entrée de programme (76, 58, 53-62) pour forcer ledit récepteur à arrêter l'enfude de programme (76, 78, 53-62) à commencer à arrêter en sorte ledit programme sur un émetteur de radiodiffusion ou de diffusion par câble (83, 87, 91 ou 92) à un quartième instant spécifique.
- 30 140. Appareil de station d'émetteur selon la revendication 139, comprenant en outre:
- une huitième mémoire (73) ou un huitième enregistreur (76 ou 78) pour stocker une ou plusieurs données qui désignent le point de début d'une partie d'un programme, et un second contrôleur de sonie (73, 205C dans 73, 39 dans un quelconque décodeur, 12 dans 71) connecté en fonctionnement à ledit huitième mémoire (73) et audit récepteur d'entrée de programme (76, 78, 53-62) afin de commencer l'amission en sorte d'une partie d'un programme au début de cette partie.
- 35 141. Appareil de station d'émetteur selon la revendication 139, dans lequel ledit sixième dispositif d'entrée (50-52, 74, 98) entre un signal d'instruction qui permet, au niveau de la station d'émetteur, d'émettre en sortie ledit programme:
- un cinquième processeur (73) connecté en fonctionnement audit cinquième dispositif d'entrée (50-52, 74, 98) pour distinguer un signal qui permet, au niveau de ladie station d'émetteur, d'émettre en sortie un programme, et un sixième processeur (73) connecté en fonctionnement audit sixième processeur (73) pour localiser ou iden-

lifier une certaine partie d'un programme.

142. Appareil de station d'émetteur selon la revendication 139, dans lequel ledit émetteur (50-62, 74, 98) reçoit depuis une quatrième station à distance un signal d'instruction qui permet, au niveau de la station d'émetteur, d'envoyer en sortie ledit programme audio sur une ligne instant spécifique.
143. Appareil de station d'émetteur selon l'une quelconque des revendications 117 à 142, dans lequel ledit récepteur d'entrée de programme (76, 78, 53-62) reçoit un signal qui contient au moins une partie dudit programme et qui contient des données moyées qui identifient ledit programme ou qui désignent le point de début d'une certaine partie dudit programme ou qui comprend un message associé auditi programme, ledit appareil comprenant en outre:
- un décodeur numérique (24, 37, 38, 43 ou 44 dans un quelconque décodeur) connecté en fonctionnement audit récepteur d'entrée de programme (76, 78, 53-62) pour détecter des données moyées dans un signal;
 - un appareil de station d'émetteur selon l'une quelconque des revendications 117 à 142, dans lequel un message associé auditi programme, qui contient une programmation vidéo, audio ou l'ordinateur ou un fichier vidéo, audio ou de données est communiquée à ou est stockée au niveau dudit récepteur d'entrée de programme (76, 78, 53-62) avant ledit instant spécifique nommée en premier, ledit appareil comprenant en outre:
 - un septième processeur (73, 35) dans un quelconque décodeur) pour traiter un ou plusieurs de ces messages;
144. Appareil de station d'émetteur selon l'une quelconque des revendications 117 à 143, dans lequel un message qui contient une programmation vidéo, audio ou l'ordinateur ou un fichier vidéo, audio ou de données est stockée au niveau dudit récepteur d'entrée de programme (76, 78, 53-62) avant ledit instant spécifique nommée en premier, ledit appareil comprenant en outre:
- un septième processeur (73, 35) dans un quelconque décodeur) pour traiter un ou plusieurs de ces messages;
145. Appareil de station d'émetteur selon l'une quelconque des revendications 117 à 144, dans lequel un message qui contient une commande associée auditi programme est communiquée à ou est stockée au niveau dudit récepteur d'entrée de programme (76, 78, 53-62) avant ledit instant spécifique nommée en premier, ledit appareil comprenant en outre un dispositif pris parmi:
- un huitième processeur (39) dans un quelconque décodeur) pour distinguer une commande dans un message associé à un programme; et
 - un premier contrôleur d'émission (73, 39 dans un quelconque décodeur, 12 dans 71) connecté en fonctionnement audit dixième processeur (35) dans un quelconque décodeur) pour commander un certain appareil en réponse à une telle commande dans un message.
146. Appareil de station d'émetteur selon l'une quelconque des revendications 117 à 145, dans lequel un message qui contient un segment de mesure-surveillance associé auditi programme est communiquée à ou est stockée au niveau dudit récepteur d'entrée de programme (76, 78, 53-62), ledit appareil comprenant en outre un dispositif pris parmi:
- un neuvième processeur (35) dans un quelconque décodeur) pour distinguer un segment de mesure-surveillance dans un message associé à un programme; et
 - un dixième processeur (en 71, 96) connecté en fonctionnement audit onzième processeur (35) dans un quelconque décodeur) pour assembler ou stocker des fichiers de mesure ou des fichiers de surveillance qui incluent en évènement la manipulation ou l'émission d'un programme ou d'un message associé à un programme.
147. Appareil de station d'émetteur selon l'une quelconque des revendications 117 à 146, dans lequel un message associé auditi programme qui contient un champ d'en-tête ou de format est communiquée à ou est stockée au niveau dudit récepteur d'entrée de programme (76, 78, 53-62), ledit appareil comprenant en outre:
- un onzième processeur (35) dans un quelconque décodeur) pour distinguer le format, le contenu ou la fin d'une certaine partie d'un message associé à un programme sur la base d'un champ d'en-tête ou de format.
148. Appareil de station d'émetteur selon l'une quelconque des revendications 117 à 147, dans lequel un message associé auditi programme qui contient un signal de fin de fichier ou une interruption de programme est communiquée à ou est stockée au niveau dudit récepteur d'entrée de programme (76, 78, 53-62), ledit appareil comprenant en outre:
- un détecteur de signal (39F ou 39H dans un quelconque décodeur) pour détecter un signal de fin de fichier ou pour communiquer une interruption de programme associée à un programme de radiodiffusion ou de diffusion par câble; et
 - un douzième processeur (73, 35) dans un quelconque décodeur) connecté en fonctionnement audit décodeur de signal (39F ou 39H dans un quelconque décodeur) pour répondre à une interruption de programme associée

à un programme de radiodiffusion ou de diffusion par câble.

149. Appareil de station d'émetteur selon l'une quelconque des revendications 117 à 148, comprenant en outre, un troisième ordinateur (73) connecté en fonctionnement à un émetteur (83, 87, 91 ou 92) pour générer et communiquer un message qui doit être associé à un programme et qui inclut une certaine programmation visée, audio ou d'ordinateur ou un fichier vidéo, audio ou de données.
150. Appareil de station d'émetteur selon l'une quelconque des revendications 117 à 149, comprenant en outre:
- un quatrième ordinateur (73) connecté en fonctionnement à un émetteur (83, 87, 91 ou 92) pour générer et communiquer une certaine partie d'une commande et pour communiquer ladite commande dans un message à associer à un programme.
151. Appareil de station d'émetteur selon l'une quelconque des revendications 117 à 150, comprenant en outre:
- un cinquième ordinateur (73) connecté en fonctionnement à un émetteur (83, 87, 91 ou 92) pour générer et communiquer une certaine partie d'un segment de mesure-surveillance à associer avec un programme.
152. Appareil de station d'émetteur selon l'une quelconque des revendications 117 à 151, comprenant en outre:
- un sixième ordinateur (73) connecté en fonctionnement à un émetteur (83, 87, 91 ou 92) pour générer une certaine partie d'un message présentant un format spécifique et à associer à un programme et pour communiquer ladite partie d'un message avec un champ d'en-tête ou de format qui désigne ledit format spécifique.
153. Appareil de station d'émetteur selon l'une quelconque des revendications 117 à 152, comprenant en outre:
- un septième ordinateur (73) connecté en fonctionnement audit décodeur d'entrée de programme (76, 78, 53-62) à un émetteur (83, 87, 91 ou 92) pour générer un message associé à un programme et contenir une interruption de programme.
154. Appareil de station d'émetteur selon l'une quelconque des revendications 139 et 140 à 153 lorsqu'il elle dépend de la revendication 139, comprenant en outre:
- un huitième dispositif d'émission sélective (73 ou 75), connecté en fonctionnement à un ou plusieurs dispositifs d'entrée (50-52, 71, 73, 74, 98) et audit récepteur d'entrée de programme (76, 78, 53-62) pour communiquer audit récepteur d'entrée de programme et associer audit programme, une ou plusieurs données qui identifient ledit programme, une ou plusieurs données dudit programme ou un signal qui permet, au niveau de la station de réception, d'appliquer une instruction.
155. Appareil de station d'émetteur selon l'une quelconque des revendications 117 à 154, dans lequel ledit programme est communiquée à et est stocké au niveau dudit récepteur d'entrée de programme (76, 78, 53-62) avant tout instant spécifique nommé en premier, ledit appareil comprenant en outre:
- un second récepteur d'entrée de programme (78, 53-62) connecté en fonctionnement à un dispositif d'entrée (73 ou 75) pour communiquer un programme audit récepteur d'entrée de programme nommé en premier (76, 78, 53-62);
156. Appareil de station d'émetteur selon la revendication 120 et l'une quelconque des revendications 121 à 155, lorsque elle dépend de la revendication 120, dans lequel ledit récepteur d'entrée de programme nommé en premier instant spécifique nommé en premier, ledit appareil comprenant en outre:
- un second récepteur d'entrée de programme (78, 53-62) connecté en fonctionnement à un dispositif d'entrée (73 ou 75) pour communiquer un programme audit récepteur d'entrée de programme nommé en premier (76, 78, 53-62),
157. Appareil de station d'émetteur selon la revendication 120 et l'une quelconque des revendications 121 à 155, lorsque elle dépend de la revendication 120, dans lequel ledit récepteur d'entrée de programme (73) ou un enregistreur (76 ou 78) pour décoder une information codée dans un signal stocké.
158. Appareil de station d'émetteur selon la revendication 120, dans lequel ledit récepteur d'entrée de programme nommé en premier instant spécifique nommé en premier, ledit appareil comprenant en outre:
- un second processeur de commande (39) dans 77, 39 dans 79, 73) pour distinguer un signal stocké décodé qui permet, au niveau de la station d'émission, d'appliquer une instruction;
 - un neuvième dispositif d'émission sélective (39) dans 77, 39 dans 79) connecté en fonctionnement audit second processeur de commande (39) dans 77, 39 dans le second décodeur (77, 7, 9) pour communiquer un second décodeur (77, 79) connecté en fonctionnement à une mémoire (73) ou un enregistreur (76 ou 78) pour décoder une information codée dans un signal stocké;
 - un troisième contrôleur de sortie (39 dans 77, 39 dans 79, 73) pour commander ledit neuvième dispositif d'émission sélective (39) dans 77, 39 dans 79) afin de communiquer un signal d'instruction de décodeur à un contrôleur spécifique (73, 205C, 39 dans un quelconque décodeur) ou à un ordinateur (73); et
 - un quatrième dispositif d'émission sélective (39) dans 77, 39 dans 79) connecté en fonctionnement audit deuxième dispositif d'émission sélective (39) dans 77, 39 dans 79) pour commander ledit quatrième enregistreur (76 ou 78).

- † 157. Appareil de station d'émetteur selon la revendication 156, comprenant en outre:
un traiteur processeur (en 71, 73, dans 39 d'un quelconque décodeur) connecté en fonctionnement à un contrôleur (73, 205C, 39 étant un quelconque décodeur) ou à un ordinateur (73) pour distinguer un décodeur spécifique (n° 1, 77, 79, 80, 84, 86) ou pour communiquer une donnée désignant un récepteur à l'entête de programme spécifique (76, 78, 53-62).
- 5 158. Appareil de station d'émetteur selon la revendication 155 et selon l'une quelconque des revendications 156 et 157 lorsqu'elle dépend de la revendication 155, comprenant en outre un dispositif pris parti:
- 10 un premier commutateur (75) connecté en fonctionnement audi second émetteur de radiodiffusion ou de diffusion par câble (83, 87, 91, 92) pour communiquer des signaux sélectivement depuis ledit récepteur d'entrée de programme nommé en premier (76, 78, 53-62) et ledit second récepteur d'entrée de programme (78, 53-62); et un second commutateur (75) connecté en fonctionnement audi second récepteur d'entrée de programme nommé en premier (76 ou 78) et audi émetteur de radiodiffusion ou de diffusion par câble (83, 87, 91, 92).
- 15 159. Appareil de station d'émetteur selon la revendication 158, dans lequel ledit premier commutateur (75) ou ledit second commutateur (75) est commandé par ledit contrôleur central (73).
- 20 160. Appareil de station d'émetteur selon l'une quelconque des revendications 117 à 159, dans lequel ladite station d'émetteur inclut une pluralité de décodeurs d'entrée de programme (53-62) pour recevoir des signaux depuis une ou plusieurs sources de programmation à distance ou une pluralité de mémoires (73) ou d'enregistreurs (76 et 78) pour stocker des signaux ou une pluralité d'émetteurs de radiodiffusion ou de diffusion par câble (83, 97, 91, 92), ledit appareil comprenant en outre:
un commutateur matriciel (75) ou un commutateur numérique (39) dans un quelconque décodeur) permettant de communiquer une pluralité de signaux simultanément.
- 25 161. Appareil de station d'émetteur selon la revendication 160 et qui s'y dépend de la revendication 123, dans lequel ledit commutateur matriciel (75) ou ledit commutateur numérique (39) dans un quelconque décodeur, est commandé par ledit contrôleur central (73).
- 30 162. Appareil de station d'émetteur selon l'une quelconque des revendications 117 à 161, comprenant en outre:
un générateur de signal (82, 86, 90) connecté en fonctionnement audi émetteur de radiodiffusion ou de diffusion par câble (83, 87, 91, 90) pour recevoir ledit signal de commande et pouroyer ledit signal de commande dans ladite émission d'information.
- 35 163. Appareil de station d'émetteur selon la revendication 162 et qui s'y dépend de la revendication 153, dans lequel ledit signal de commande est communiqué audi générateur de signal (82, 86, 90) au moyen d'un dispositif quelconque pris namfi ledit troisième ordinateur (73), ledit quatrième ordinateur (73), ledit cinquième ordinateur (73), ledit sixième ordinateur (73) et ledit septième ordinateur (73).
- 40 164. Appareil de station d'émetteur selon l'une quelconque des revendications 117 à 153, dans lequel ladite émission d'information comprend une pluralité de canaux de programmation de télévision, alors de programmation de radio, ledit appareil comprenant en outre:
une pluralité de modulateurs (83, 87, 91), chaque modulateur (83, 87, 91) étant connecté en fonctionnement à un récepteur d'entrée de programme (76, 78, 53-62) pour moduler un canal, et un système de multiplexage (92) connecté en fonctionnement audi émetteur de radiodiffusion ou de diffusion par câble (83, 87, 91) pour communiquer une émission d'information comprenant une pluralité de canaux.
- 45 165. Appareil de station d'émetteur selon l'une quelconque des revendications 117 à 164, dans lequel ladite station d'émetteur comprend un ou plusieurs systèmes de processeur (71, 39 dans un quelconque décodeur) pour traiter des signaux qui contiennent des commandes et un contenu d'information de sortie de programme, ledit appareil comprenant en outre:
une ou plusieurs sections d'émetteur (12 et 39 dans chaque décodeur de 71; 39 dans chaque 39) pour émettre des commandes et/ou un contenu d'information de scote de programme sélectivement sur un ou plusieurs dispositifs de récepteur externe (72, 72, 97 dans 71; 73 et 205C dans 73);
- 50 55
